

Mechanization of the Algebra for Wireless Networks (AWN)

Timothy Bourke*

December 14, 2021

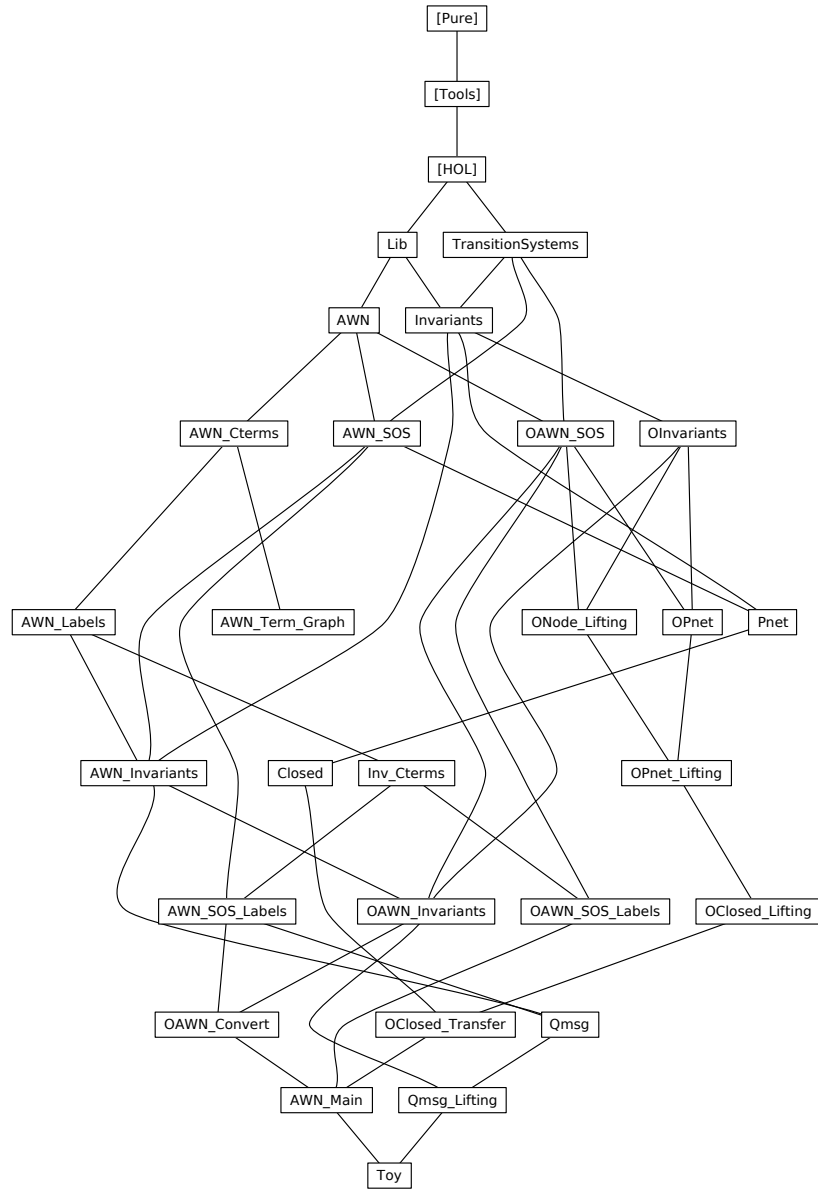

Abstract

AWN is a process algebra developed for modelling and analysing protocols for Mobile Ad hoc Networks (MANETs) and Wireless Mesh Networks (WMNs) [2, §4]. AWN models comprise five distinct layers: sequential processes, local parallel compositions, nodes, partial networks, and complete networks.

This development mechanises the original operational semantics of AWN and introduces a variant ‘open’ operational semantics that enables the compositional statement and proof of invariants across distinct network nodes. It supports labels (for weakening invariants) and (abstract) data state manipulations. A framework for compositional invariant proofs is developed, including a tactic (`inv_cterms`) for inductive invariant proofs of sequential processes, lifting rules for the open versions of the higher layers, and a rule for transferring lifted properties back to the standard semantics. A notion of ‘control terms’ reduces proof obligations to the subset of subterms that act directly (in contrast to operators for combining terms and joining processes).

Further documentation is available in [1].

4 Open reachability and invariance

```

theory OInvariants
imports Invariants
begin

```

4.1 Open reachability

By convention, the states of an open automaton are pairs. The first component is considered to be the global state and the second is the local state.

A state is ‘open reachable’ under S and U if it is the initial state, or it is the destination of a transition—where the global components satisfy S —from an open reachable state, or it is the destination of an interleaved environment step where the global components satisfy U .

5 Terms of the Algebra for Wireless Networks

```
theoryAWN
importsLib
begin
```

5.1 Sequential Processes

```
type_synonym ip = nat
type_synonym data = nat
```

Most ofAWN is independent of the type of messages, but the closed layer turns newpkt actions into the arrival of newpkt messages. We use a type class to maintain some abstraction (and independence from the definition of particular protocols).

```
class msg =
  fixes newpkt :: "data × ip ⇒ 'a"
  and eq_newpkt :: "'a ⇒ bool"
  assumes eq_newpkt_eq [simp]: "eq_newpkt (newpkt (d, i))"
```

Sequential process terms abstract over the types of data states ('s), messages ('m), process names ('p), and labels ('l).

```
datatype (dead 's, dead 'm, dead 'p, 'l) seqp =
  GUARD "'l" "'s ⇒ 's set" "('s, 'm, 'p, 'l) seqp"
| ASSIGN "'l" "'s ⇒ 's" "('s, 'm, 'p, 'l) seqp"
| CHOICE "('s, 'm, 'p, 'l) seqp" "('s, 'm, 'p, 'l) seqp"
| UCAST "'l" "'s ⇒ ip" "'s ⇒ 'm" "('s, 'm, 'p, 'l) seqp" "('s, 'm, 'p, 'l) seqp"
| BCAST "'l" "'s ⇒ 'm" "('s, 'm, 'p, 'l) seqp"
| GCAST "'l" "'s ⇒ ip set" "'s ⇒ 'm" "('s, 'm, 'p, 'l) seqp"
| SEND "'l" "'s ⇒ 'm" "('s, 'm, 'p, 'l) seqp"
| DELIVER "'l" "'s ⇒ data" "('s, 'm, 'p, 'l) seqp"
| RECEIVE "'l" "'m ⇒ 's ⇒ 's" "('s, 'm, 'p, 'l) seqp"
| CALL 'p
for map: labelmap
```

7.2 Wellformed process specifications

A process specification Γ is wellformed if its *microstep* Γ relation is free of loops and infinite chains.

For example, these specifications are not wellformed: Γ_1 $p1 = \text{call}(p1)$

Γ_2 $p1 = \text{send}(msg) . \text{call}(p1) \oplus \text{call}(p1)$

Γ_3 $p1 = \text{send}(msg) . \text{call}(p2)$ Γ_3 $p2 = \text{call}(p3)$ Γ_3 $p3 = \text{call}(p4)$ Γ_3 $p4 = \text{call}(p5) \dots$

definition

```
wellformed :: "('s, 'm, 'p, 'l) seqp_env  $\implies$  bool"
```

where

```
"wellformed  $\Gamma$  = wf {(q, p). p  $\rightsquigarrow_{\Gamma}$  q}"
```

```
lemma wellformed_defP: "wellformed  $\Gamma$  = wfP ( $\lambda$ q p. p  $\rightsquigarrow_{\Gamma}$  q)"
```

```
unfolding wellformed_def wfP_def by simp
```

The induction rule for *wellformed* Γ is stronger than $\llbracket \bigwedge x_1 x_2 x_3. ?P x_3 \implies ?P (\{x_1\}(x_2) x_3); \bigwedge x_1 x_2 x_3. ?P x_3 \implies ?P (\{x_1\}[\![x_2]\!] x_3); \bigwedge x_1 x_2. \llbracket ?P x_1; ?P x_2 \rrbracket \implies ?P (x_1 \oplus x_2); \bigwedge x_1 x_2 x_3 x_4 x_5. \llbracket ?P x_4; ?P x_5 \rrbracket \implies ?P (\{x_1\}unicast(x_2, x_3) . x_4 \triangleright x_5); \bigwedge x_1 x_2 x_3. ?P x_3 \implies ?P (\{x_1\}broadcast(x_2) . x_3); \bigwedge x_1 x_2 x_3 x_4. ?P x_4 \implies ?P (\{x_1\}groupcast(x_2, x_3) . x_4); \bigwedge x_1 x_2 x_3. ?P x_3 \implies ?P (\{x_1\}send(x_2) . x_3); \bigwedge x_1 x_2 x_3. ?P x_3 \implies ?P (\{x_1\}deliver(x_2) . x_3); \bigwedge x_1 x_2 x_3. ?P x_3 \implies ?P (\{x_1\}receive(x_2) . x_3); \bigwedge x. ?P (call(x)) \rrbracket \implies ?P ?seqp$ because the case for *call*(pn) can be shown with the assumption on Γ pn.

7.5 Derivative terms

The derivatives of a term are those *sterms* potentially reachable by taking a transition, relative to a wellformed process specification Γ . These terms overapproximate the reachable terms, since the truth of guards is not considered.

```

Note that the converse of $\llbracket \text{wellformed } ?\Gamma; \exists pn. ?p \in \text{subterms } (?\Gamma \text{ } pn); ?q \in \text{dterms } ?\Gamma \text{ } ?p \rrbracket \implies \exists pn. ?q \in \text{subterms } (?\Gamma \text{ } pn)$ is not true because *dterms* are an over-approximation; i.e., we cannot show, in general, that

guards return a non-empty set of post-states.

7.6 Control terms

The control terms of a process specification Γ are those subterms from which transitions are directly possible. We can omit $call(pn)$ terms, since the root terms of all processes are considered, and also $p1 \oplus p2$ terms since they effectively combine the transitions of the subterms $p1$ and $p2$.

It will be shown that only the control terms, rather than all subterms, need be considered in invariant proofs.

7.7 Local control terms

We introduce a ‘local’ version of `cterm s` that does not step through calls and, thus, that is defined independently of a process specification Γ . This allows an alternative, terminating characterisation of `cterm s` as a set of subterms. Including `call(pn)`s in the set makes for a simpler relation with `stermsl`, even if they must be filtered out for the desired characterisation.

function

```
cterm sl :: "('s, 'm, 'p, 'l) seqp  $\implies$  ('s, 'm, 'p, 'l) seqp set"
```

where

```

"cterm sl  $\{\!|\}\langle g \rangle p$ " = insert  $\{\!|\}\langle g \rangle p$  (cterm sl p)"
| "cterm sl  $\{\!|\}\llbracket u \rrbracket p$ " = insert  $\{\!|\}\llbracket u \rrbracket p$  (cterm sl p)"
| "cterm sl  $\{\!|\}\text{unicast}(s_{ip}, s_{msg}). p \triangleright q$ " = insert  $\{\!|\}\text{unicast}(s_{ip}, s_{msg}). p \triangleright q$ 
      (cterm sl p  $\cup$  cterm sl q)"
| "cterm sl  $\{\!|\}\text{broadcast}(s_{msg}). p$ " = insert  $\{\!|\}\text{broadcast}(s_{msg}). p$  (cterm sl p)"

7.9 More properties of control terms

We now show an alternative definition of *cterms* based on sets of local control terms. While the original definition has convenient induction and simplification rules, useful for proving properties like `cterms_includes_sterms_of_seq_reachable`, this definition makes it easier to systematically generate the set of control terms of a process specification.

```

The *simple_labels* Γ property is necessary to transfer results shown over the *cterms* of a process specification Γ to the reachable actions of that process.

Consider the process $\{l_1\}\text{send}(m1) . p1 \oplus \{l_2\}\text{send}(m2) . p2$. The iteration over *cterms* Γ will cover the two transitions $(l_1, \text{send } m1, p1)$ and $(l_2, \text{send } m2, p2)$, but reachability requires the four transitions $(l_1, \text{send } m1, p1)$, $(l_1, \text{send } m2, p2)$, $(l_2, \text{send } m1, p1)$, and $(l_2, \text{send } m2, p2)$.

In a simply labelled process, the former is sufficient to show the latter, since $l_1 = l_2$.

This requirement seems really only to be restrictive for processes where a *call*(*pn*) occurs as a direct subterm of a choice operator. Consider, for instance, $\{l_1\}[\![e]\!] \ p \oplus \text{call}(pn)$. Here l_1 must equal the label of $\Gamma \ pn$, which can then not be distinguished from any other subterm that calls *pn* in any other process.

This limitation stems from the fact that the "call points" of a process are effectively treated as the root of the called process. This is by design; we try to treat call sites as "syntactic pastings" of process terms, giving rise, conceptually, to an infinite tree structure. But this prejudices the alternative view that process calls are used as "join points" of "process threads", in complement to the "fork points" of the $p1 \oplus p2$ operator.

9 A custom tactic for showing invariants via control terms

```

theory Inv_Cterms
imports AWN_Labels
begin

```

This tactic tries to solve a goal by reducing it to a problem over (local) cterms (using one of the cterms_intros intro rules); expanding those to consider all process names (using one of the ctermssl_cases destruction rules); simplifying each (using the cterms_env simplification rules); splitting them up into separate subgoals; replacing the derivative term with a variable; ‘executing’ a transition of each term; and then simplifying.

The tactic can stop after applying introduction rule (“inv_cterms (intro_only)”), or after having generated the verification condition subgoals and before having simplified them (“inv_cterms (vcs_only)”). It takes arguments to add or remove simplification rules (“simp add: lemmas”), to add forward rules on assumptions (to introduce previously proved invariants; “inv add: lemmas”), or to add elimination rules that solve any remaining subgoals (“solve: lemmas”).

To configure the tactic for a set of transition rules:

1. add elimination rules: declare seqpTEs [cterms_seqte]
2. add rules to replace derivative terms: declare elimders [cterms_elimders]

To configure the tactic for a process environment (Γ):

1. add simp rules: declare Γ .simps [cterms_env]
2. add case rules: declare aadv_proc_cases [ctermssl_cases]
3. add invariant intros declare seq_invariant_ctermsI [OF aadv_wf aadv_control_within aadv_simple_labels, cterms_intros] seq_step_invariant_ctermsI [OF aadv_wf aadv_control_within aadv_simple_labels, cterms_intros]

'Splitting' reachability is trivial when there are no assumptions on interleavings, but this is useless for showing
non-trivial properties, since the interleaving steps can do anything at all. This lemma is too weak.

It may also be tempting to try splitting from the assumption $(\sigma, \text{SubnetS } s_1 s_2) \in \text{oreachable } (\text{opnet onp } (p_1 \parallel p_2))$ $(\lambda_ _ _ . \text{True})$ $(\lambda_ _ _ . \text{False})$, where the environment step would be trivially true (since the assumption is false), but the lemma cannot be shown when only one side acts, since it must guarantee the assumption for the other side.
