# Comparison-based Sorting Algorithms

Manuel Eberl  
April 19, 2020

## Abstract

This article contains a formal proof of the well-known fact that the number of comparisons that a comparison-based sorting algorithm needs to perform to sort a list of length $n$ is at least $\log_2(n!)$ in the worst case, i.e. $\Omega(n \log n)$.

For this purpose, a shallow embedding for comparison-based sorting algorithms is defined: a sorting algorithm is a recursive datatype containing either a HOL function or a query of a comparison oracle with a continuation containing the remaining computation. This makes it possible to force the algorithm to use only comparisons and to track the number of comparisons made.

\[ \text{shows } xs = ys \]
(proof)

1.6 Obtaining a sorted list of a given set

definition sorted-wrt-list-of-set where
\[ \text{sorted-wrt-list-of-set R } A = \]
\[ \text{(if finite } A \text{ then } (\text{THE } xs. \text{ set } xs = A \land \text{distinct } xs \land \text{sorted-wrt R } xs) \text{ else } []) \]

lemma mset-remdups: \( \text{mset } (\text{remdups } xs) = \text{mset-set } (\text{set } xs) \)
(proof)

lemma sorted-wrt-list-set:
\[ \text{assumes } \text{linorder-on } A R \text{ set } xs \subseteq A \]
\[ \text{shows } \text{sorted-wrt-list-of-set R } (\text{set } xs) = \text{insort-wrt R } (\text{remdups } xs) \]
(proof)

lemma linorder-sorted-wrt-exists:
\[ \text{assumes } \text{linorder-on } A R \text{ finite } B B \subseteq A \]
\[ \text{shows } \exists xs. \text{ set } xs = B \land \text{distinct } xs \land \text{sorted-wrt R } xs \]
(proof)

lemma linorder-sorted-wrt-list-of-set:
\[ \text{assumes } \text{linorder-on } A R \text{ finite } B B \subseteq A \]
\[ \text{shows } \text{set } (\text{sorted-wrt-list-of-set R } B) = B \land \text{distinct } (\text{sorted-wrt-list-of-set R } B) \]
\[ \text{sorted-wrt R } (\text{sorted-wrt-list-of-set R } B) \]
(proof)

lemma sorted-wrt-list-of-set-eqI:
\[ \text{assumes } \text{linorder-on } B R A \subseteq B \text{ set } xs = A \text{ distinct } xs \text{ sorted-wrt R } xs \]
\[ \text{shows } \text{sorted-wrt-list-of-set R } A = xs \]
(proof)

5
1.7 Rank of an element in an ordering

The ‘rank’ of an element in a set w.r.t. an ordering is how many smaller elements exist. This is particularly useful in linear orders, where there exists a unique $n$-th element for every $n$.

**Definition linorder-rank where**

\[ \text{linorder-rank} \ R \ A \ x = \text{card} \ \{y \in A - \{x\}. \ (y,x) \in R\} \]

**Lemma linorder-rank-le:**

- **Asumes** finite $A$
- **Shows** $\text{linorder-rank} \ R \ A \ x \leq \text{card} \ A$

**Lemma linorder-rank-less:**

- **Asumes** finite $A$ $x \in A$
- **Shows** $\text{linorder-rank} \ R \ A \ x < \text{card} \ A$

**Lemma linorder-rank-union:**

- **Asumes** finite $A$ finite $B$ $A \cap B = \{\}$
- **Shows** $\text{linorder-rank} \ R \ (A \cup B) \ x = \text{linorder-rank} \ R \ A \ x + \text{linorder-rank} \ R \ B \ x$

**Lemma linorder-rank-empty [simp]:** $\text{linorder-rank} \ R \ \{\} \ x = 0$

**Lemma linorder-rank-singleton:**

\[ \text{linorder-rank} \ R \ \{y\} \ x = \begin{cases} 0 & \text{if } x \neq y \land (y,x) \in R \text{ then } 1 \text{ else } 0 \end{cases} \]

**Lemma linorder-rank-insert:**

- **Asumes** finite $A$ $y \notin A$
- **Shows** $\text{linorder-rank} \ R \ (\text{insert } y \ A) \ x = \begin{cases} 1 & \text{if } x \neq y \land (y,x) \in R \text{ then } 1 \text{ else } 0 \end{cases} + \text{linorder-rank} \ R \ A \ x$

**Lemma linorder-rank-mono:**

- **Asumes** linorder-on $B \ R$ finite $A$ $A \subseteq B$ $(x, y) \in R$
- **Shows** $\text{linorder-rank} \ R \ A \ x \leq \text{linorder-rank} \ R \ A \ y$

**Lemma linorder-rank-strict-mono:**

- **Asumes** linorder-on $B \ R$ finite $A$ $A \subseteq B$ $y \in A$ $(y, x) \in R$ $x \neq y$
- **Shows** $\text{linorder-rank} \ R \ A \ y < \text{linorder-rank} \ R \ A \ x$

**Lemma linorder-rank-le-iff:**

- **Asumes** linorder-on $B \ R$ finite $A$ $A \subseteq B$ $x \in A$ $y \in A$
shows \( \text{linorder-rank} \, R \, A \, x \leq \text{linorder-rank} \, R \, A \, y \iff (x, y) \in R \) 

\langle proof \rangle

lemma \text{linorder-rank-eq-iff}:

begin

2.1 Abstract description of sorting algorithms

We have chosen to model a sorting algorithm in the following way: A sorting algorithm takes a list with distinct elements and a linear ordering on these
elements, and it returns a list with the same elements that is sorted w. r. t. the given ordering.

The use of an explicit ordering means that the algorithm must look at the ordering, i.e. it has to use pair-wise comparison of elements, since all the information that is relevant for producing the correct sorting is in the ordering; the elements themselves are irrelevant.

Furthermore, we record the number of comparisons that the algorithm makes by not giving it the relation explicitly, but in the form of a comparison oracle that may be queried.

A sorting algorithm (or ‘sorter’) for a fixed input list (but for arbitrary orderings) can then be written as a recursive datatype that is either the result (the sorted list) or a comparison query consisting of two elements and a continuation that maps the result of the comparison to the remaining computation.

\[
\text{datatype } a \text{ sorter} = \text{Return } a \text{ list } | \text{Query } a a \text{ bool } \Rightarrow a \text{ sorter}
\]

Cormen et al. [1] use a similar ‘decision tree’ model where an sorting algorithm for lists of fixed size \( n \) is modelled as a binary tree where each node is a comparison of two elements. They also demand that every leaf in the tree be reachable in order to avoid ‘dead’ subtrees (if the algorithm makes redundant comparisons, there may be branches that can never be taken).

Then, the worst-case number of comparisons made is simply the height of the tree.

We chose a subtly different model that does not have this restriction on the algorithm but instead uses a more semantic way of counting the worst-case number of comparisons: We simply use the maximum number of comparisons that occurs for any of the (finitely many) inputs.

We therefore first define a function that counts the number of queries for a specific ordering and then a function that counts the number of queries in the worst case (ranging over a given set of allowed orderings; typically, this will be the set of all linear orders on the list).

\[
\text{primrec count-queries :: } (a \times a) \text{ set } \Rightarrow a \text{ sorter } \Rightarrow \text{nat where}
\]
\[
\begin{align*}
\text{count-queries} - (\text{Return } -) &= 0 \\
\text{count-queries} R (\text{Query } a b f) &= \text{Suc} (\text{count-queries} R (f ((a, b) \in R)))
\end{align*}
\]

\[
\text{definition count-wc-queries :: } (a \times a) \text{ set set } \Rightarrow a \text{ sorter } \Rightarrow \text{nat where}
\]
\[
\begin{align*}
\text{count-wc-queries} R s \text{ sorter} &= (\text{if } R s = \{\} \text{ then } 0 \text{ else } \text{Max} ((\lambda R. \text{count-queries} R \text{ sorter}) ' R s))
\end{align*}
\]

\[
\text{lemma count-wc-queries-empty [simp]: count-wc-queries } \{\} \text{ sorter } = 0
\]
\[
\langle \text{proof}\rangle
\]

\[
\text{lemma count-wc-queries-aux:}
\]
\[
\text{assumes } \land R. R \in R s \Rightarrow \text{sorter } = \text{sorter } R s \subseteq R s ^{\prime} \text{ finite } R s ^{\prime}
\]

8
shows \( \text{count-wc-queries } R \text{ sorter} \leq \text{Max } ((\lambda R. \text{count-queries } R (\text{sorter'} R)) ^ \circ R s') \)

\( \langle \text{proof} \rangle \)

\textbf{primrec} \text{eval-sorter} :: ('a × 'a) \text{ set} ⇒ 'a \text{ sorter} ⇒ 'a \text{ list} \text{ where}

\text{eval-sorter} - (\text{Return } ys) = ys
| \text{eval-sorter} R (\text{Query } a \ b \ f) = \text{eval-sorter} R (f ((a, b) \in R))

We now get an obvious bound on the maximum number of different results that a given sorter can produce.

\textbf{lemma} \text{card-range-eval-sorter}:

\text{assumes} \text{finite } R s
\text{shows} \text{card } ((\lambda R. \text{eval-sorter } R e) ^ \circ R s) \leq 2 ^ \text{count-wc-queries } R s e

\( \langle \text{proof} \rangle \)

The following predicate describes what constitutes a valid sorting result for a given ordering and a given input list. Note that when the ordering is linear, the result is actually unique.

\textbf{definition} \text{is-sorting} :: ('a × 'a) \text{ set} ⇒ 'a \text{ list} ⇒ 'a \text{ list} ⇒ \text{bool} \text{ where}

\text{is-sorting } R \text{ xs ys} \leftrightarrow (\text{mset } \text{xs} = \text{mset } \text{ys}) \land \text{sorted-wr R ys}

2.2 Lower bounds on number of comparisons

For a list of \(n\) distinct elements, there are \(n!\) linear orderings on \(n\) elements, each of which leads to a different result after sorting the original list. Since a sorter can produce at most \(2^k\) different results with \(k\) comparisons, we get the bound \(2^k \geq n!\):

\textbf{theorem}

\text{fixes} \text{sorter} :: 'a \text{ sorter} \text{ and } \text{xs} :: 'a \text{ list}
\text{assumes} \text{distinct: } \text{distinct } \text{xs}
\text{assumes} \text{sorter: } \bigwedge R. \text{linorder-on } (\text{set } \text{xs}) R \implies \text{is-sorting } R \text{ xs } (\text{eval-sorter } R \text{ sorter})
\text{defines} \text{Rs} \equiv \{ R. \text{linorder-on } (\text{set } \text{xs}) R \}
\text{shows} \text{two-power-count-queries-ge: } \text{fact } (\text{length } \text{xs}) \leq (2 ^ \text{count-wc-queries } \text{Rs sorter} : \text{nat})
\text{and} \text{count-queries-ge: } \log_2 (\text{fact } (\text{length } \text{xs})) \leq \text{real } (\text{count-wc-queries } \text{Rs sorter})
\( \langle \text{proof} \rangle \)

\textbf{lemma} \text{ln-fact-bigo} : (\lambda n. \ln (\text{fact } n) - (\ln (2 * \pi * n) / 2 + n * \ln n - n)) \in O(\lambda n. 1 / n)
\text{and} \text{asym-equiv-ln-fact} [\text{asym-equiv-intros}]: (\lambda n. \ln (\text{fact } n)) \sim [\text{at-top}] (\lambda n. n \ast \ln n)
\( \langle \text{proof} \rangle \)
\text{include} \text{asym-equiv-notation}
\( \langle \text{proof} \rangle \)
This leads to the following well-known Big-Omega bound on the number of comparisons that a general sorting algorithm has to make:

**corollary count-queries-bigomega:**

**fixes** sorter :: nat ⇒ nat sorter

**assumes** sorter: \(\forall n. \text{linorder-on } \{..<n\} R \implies \text{is-sorting } R [0..<n] (\text{eval-sorter } R (\text{sorter } n))\)

**defines** \(Rs \equiv \lambda n. \{R. \text{linorder-on } \{..<n\} R\}\)

**shows** \((\lambda n. \text{count-wc-queries } (Rs n) (\text{sorter } n)) \in \Omega(\lambda n. n \ast \ln n)\)

\(\langle \text{proof} \rangle\)

end
