# Comparison-based Sorting Algorithms

### Manuel Eberl

March 17, 2025

#### Abstract

This article contains a formal proof of the well-known fact that number of comparisons that a comparison-based sorting algorithm needs to perform to sort a list of length n is at least  $\log_2(n!)$  in the worst case, i. e.  $\Omega(n \log n)$ .

For this purpose, a shallow embedding for comparison-based sorting algorithms is defined: a sorting algorithm is a recursive datatype containing either a HOL function or a query of a comparison oracle with a continuation containing the remaining computation. This makes it possible to force the algorithm to use only comparisons and to track the number of comparisons made.

#### 1.4 Converting a list into a linear ordering

**definition** linorder-of-list :: 'a list  $\Rightarrow$  ('a  $\times$  'a) set where linorder-of-list  $xs = \{(a,b). a \in set xs \land b \in set xs \land index xs a \leq index xs b\}$ 

```
lemma linorder-linorder-of-list [intro, simp]:
assumes distinct xs
shows linorder-on (set xs) (linorder-of-list xs)
⟨proof⟩
```

**lemma** sorted-wrt-linorder-of-list [intro, simp]: distinct  $xs \implies$  sorted-wrt (linorder-of-list xs) xs $\langle proof \rangle$ 

#### 1.5 Insertion sort

**primrec** insert-wrt ::  $('a \times 'a)$  set  $\Rightarrow 'a \Rightarrow 'a$  list  $\Rightarrow 'a$  list where insert-wrt  $R x \parallel = [x]$ 

| insert-wrt R x (y # ys) = (if (x, y)  $\in$  R then x # y # ys else y # insert-wrt R x ys)

**lemma** set-insert-wrt [simp]: set (insert-wrt  $R \ x \ xs$ ) = insert x (set xs)  $\langle proof \rangle$ 

**lemma** mset-insert-wrt [simp]: mset (insert-wrt R x xs) = add-mset x (mset xs)  $\langle proof \rangle$ 

**lemma** length-insert-wrt [simp]: length (insert-wrt  $R \ x \ xs$ ) = Suc (length xs)  $\langle proof \rangle$ 

**definition** insort-wrt ::  $('a \times 'a)$  set  $\Rightarrow$  'a list  $\Rightarrow$  'a list where insort-wrt R xs = foldr (insert-wrt R) xs []

**lemma** set-insort-wrt [simp]: set (insort-wrt R xs) = set  $xs \langle proof \rangle$ 

**lemma** mset-insort-wrt [simp]: mset (insort-wrt R xs) = mset  $xs \langle proof \rangle$ 

**lemma** length-insort-wrt [simp]: length (insort-wrt R xs) = length xs

 $\langle proof \rangle$ 

**lemma** sorted-wrt-insort [intro]: **assumes** linorder-on  $A \ R \ set \ xs \subseteq A$  **shows** sorted-wrt  $R \ (insort-wrt \ R \ xs)$  $\langle proof \rangle$ 

**lemma** distinct-insort-wrt [simp]: distinct (insort-wrt R xs)  $\longleftrightarrow$  distinct  $xs \langle proof \rangle$ 

```
lemma sorted-wrt-linorder-unique:

assumes linorder-on A \ R \ mset \ xs = mset \ ys \ sorted-wrt \ R \ xs \ sorted-wrt \ R \ ys

shows xs = ys

\langle proof \rangle
```

#### 1.6 Obtaining a sorted list of a given set

definition *sorted-wrt-list-of-set* where sorted-wrt-list-of-set R A =(if finite A then (THE xs. set  $xs = A \land distinct xs \land sorted-wrt R xs)$  else []) **lemma** mset-remdups: mset (remdups xs) = mset-set (set xs)  $\langle proof \rangle$ **lemma** *sorted-wrt-list-set*: **assumes** linorder-on A R set  $xs \subseteq A$ **shows** sorted-wrt-list-of-set R (set xs) = insort-wrt R (remdups xs)  $\langle proof \rangle$ **lemma** *linorder-sorted-wrt-exists*: **assumes** linorder-on A R finite  $B B \subseteq A$ **shows**  $\exists xs. set xs = B \land distinct xs \land sorted-wrt R xs$  $\langle proof \rangle$ **lemma** *linorder-sorted-wrt-list-of-set*: **assumes** linorder-on A R finite  $B B \subseteq A$ **shows** set (sorted-wrt-list-of-set R B) = B distinct (sorted-wrt-list-of-set R B) sorted-wrt R (sorted-wrt-list-of-set R B)  $\langle proof \rangle$ **lemma** *sorted-wrt-list-of-set-eqI*: **assumes** linorder-on  $B \ R \ A \subseteq B$  set xs = A distinct xs sorted-wrt R xs**shows** sorted-wrt-list-of-set R A = xs $\langle proof \rangle$ 

#### 1.7 Rank of an element in an ordering

The 'rank' of an element in a set w.r.t. an ordering is how many smaller elements exist. This is particularly useful in linear orders, where there exists a unique n-th element for every n.

```
definition linorder-rank where
  linorder-rank R A x = card \{y \in A - \{x\}, (y,x) \in R\}
lemma linorder-rank-le:
 assumes finite A
 shows linorder-rank R \ A \ x \leq card \ A
 \langle proof \rangle
lemma linorder-rank-less:
 assumes finite A \ x \in A
 shows linorder-rank R A x < card A
\langle proof \rangle
lemma linorder-rank-union:
 assumes finite A finite B A \cap B = \{\}
 shows linorder-rank R (A \cup B) x = linorder-rank R A x + linorder-rank R B
x
\langle proof \rangle
lemma linorder-rank-empty [simp]: linorder-rank R {} x = 0
  \langle proof \rangle
lemma linorder-rank-singleton:
  linorder-rank R \{y\} x = (if x \neq y \land (y,x) \in R then 1 else 0)
\langle proof \rangle
lemma linorder-rank-insert:
 assumes finite A \ y \notin A
 shows
           linorder-rank R (insert y A) x =
            (if x \neq y \land (y,x) \in R \text{ then } 1 \text{ else } 0) + linorder\text{-rank } R A x
  \langle proof \rangle
lemma linorder-rank-mono:
 assumes linorder-on B R finite A \subseteq B(x, y) \in R
 shows linorder-rank R A x < linorder-rank R A y
  \langle proof \rangle
lemma linorder-rank-strict-mono:
 assumes linorder-on B R finite A \ A \subseteq B \ y \in A \ (y, x) \in R \ x \neq y
 shows linorder-rank R A y < linorder-rank R A x
\langle proof \rangle
lemma linorder-rank-le-iff:
 assumes linorder-on B R finite A \ A \subseteq B \ x \in A \ y \in A
```

**shows** linorder-rank  $R \ A \ x \leq$  linorder-rank  $R \ A \ y \longleftrightarrow (x, y) \in R$   $\langle proof \rangle$ 

**lemma** linorder-rank-eq-iff: **assumes** linorder-on B R finite  $A \ A \subseteq B \ x \in A \ y \in A$  **shows** linorder-rank R A x = linorder-rank R A  $y \longleftrightarrow x = y$  $\langle proof \rangle$ 

**lemma** linorder-rank-set-sorted-wrt: **assumes** linorder-on  $B \ R \ set \ xs \subseteq B \ sorted-wrt \ R \ xs \ x \in set \ xs \ distinct \ xs$  **shows** linorder-rank  $R \ (set \ xs) \ x = index \ xs \ x$  $\langle proof \rangle$ 

#### 1.8 The bijection between linear orderings and lists

**theorem** bij-betw-linorder-of-list: **assumes** finite A **shows** bij-betw linorder-of-list (permutations-of-set A) {R. linorder-on A R}  $\langle proof \rangle$ 

**corollary** card-finite-linorders: **assumes** finite A **shows** card {R. linorder-on A R} = fact (card A)  $\langle proof \rangle$ 

 $\mathbf{end}$ 

## 2 Lower bound on costs of comparison-based sorting

theory Comparison-Sort-Lower-Bound imports Complex-Main Linorder-Relations Stirling-Formula.Stirling-Formula Landau-Symbols.Landau-More begin

#### 2.1 Abstract description of sorting algorithms

We have chosen to model a sorting algorithm in the following way: A sorting algorithm takes a list with distinct elements and a linear ordering on these

elements, and it returns a list with the same elements that is sorted w.r.t. the given ordering.

The use of an explicit ordering means that the algorithm must look at the ordering, i. e. it has to use pair-wise comparison of elements, since all the information that is relevant for producing the correct sorting is in the ordering; the elements themselves are irrelevant.

Furthermore, we record the number of comparisons that the algorithm makes by not giving it the relation explicitly, but in the form of a comparison oracle that may be queried.

A sorting algorithm (or 'sorter') for a fixed input list (but for arbitrary orderings) can then be written as a recursive datatype that is either the result (the sorted list) or a comparison query consisting of two elements and a continuation that maps the result of the comparison to the remaining computation.

datatype 'a sorter = Return 'a list | Query 'a 'a bool  $\Rightarrow$  'a sorter

Cormen *et al.* [1] use a similar 'decision tree' model where an sorting algorithm for lists of fixed size n is modelled as a binary tree where each node is a comparison of two elements. They also demand that every leaf in the tree be reachable in order to avoid 'dead' subtrees (if the algorithm makes redundant comparisons, there may be branches that can never be taken). Then, the worst-case number of comparisons made is simply the height of the tree.

We chose a subtly different model that does not have this restriction on the algorithm but instead uses a more semantic way of counting the worst-case number of comparisons: We simply use the maximum number of comparisons that occurs for any of the (finitely many) inputs.

We therefore first define a function that counts the number of queries for a specific ordering and then a function that counts the number of queries in the worst case (ranging over a given set of allowed orderings; typically, this will be the set of all linear orders on the list).

**primec** count-queries ::  $('a \times 'a)$  set  $\Rightarrow$  'a sorter  $\Rightarrow$  nat where count-queries - (Return -) = 0

 $| \text{ count-queries } R (\text{Query } a \ b \ f) = Suc (\text{ count-queries } R \ (f \ ((a, \ b) \in R)))$ 

**definition** count-wc-queries ::  $('a \times 'a)$  set set  $\Rightarrow$  'a sorter  $\Rightarrow$  nat where count-wc-queries Rs sorter = (if Rs = {} then 0 else Max (( $\lambda R$ . count-queries R sorter) 'Rs))

**lemma** count-wc-queries-empty [simp]: count-wc-queries {} sorter = 0  $\langle proof \rangle$ 

lemma count-wc-queries-aux: assumes  $\bigwedge R$ .  $R \in Rs \implies$  sorter = sorter' R  $Rs \subseteq Rs'$  finite Rs' **shows** count-wc-queries Rs sorter  $\leq Max$  (( $\lambda R$ . count-queries R (sorter ' R)) ' Rs')  $\langle proof \rangle$ 

**primec** eval-sorter ::  $('a \times 'a)$  set  $\Rightarrow$  'a sorter  $\Rightarrow$  'a list where eval-sorter - (Return ys) = ys | eval-sorter R (Query a b f) = eval-sorter R (f ((a,b) \in R))

We now get an obvious bound on the maximum number of different results that a given sorter can produce.

**lemma** card-range-eval-sorter: **assumes** finite Rs **shows** card (( $\lambda R$ . eval-sorter R e) ' Rs)  $\leq 2$  ^ count-wc-queries Rs e  $\langle proof \rangle$ 

The following predicate describes what constitutes a valid sorting result for a given ordering and a given input list. Note that when the ordering is linear, the result is actually unique.

**definition** is-sorting ::  $('a \times 'a)$  set  $\Rightarrow$  'a list  $\Rightarrow$  'a list  $\Rightarrow$  bool where is-sorting R xs ys  $\longleftrightarrow$  (mset xs = mset ys)  $\land$  sorted-wrt R ys

#### 2.2 Lower bounds on number of comparisons

For a list of n distinct elements, there are n! linear orderings on n elements, each of which leads to a different result after sorting the original list. Since a sorter can produce at most  $2^k$  different results with k comparisons, we get the bound  $2^k \ge n!$ :

#### theorem

fixes sorter :: 'a sorter and xs :: 'a list assumes distinct: distinct xsassumes sorter:  $\land R$ . linorder-on (set xs)  $R \implies$  is-sorting R xs (eval-sorter Rsorter) defines  $Rs \equiv \{R. \text{ linorder-on (set } xs) R\}$ shows two-power-count-queries-ge: fact (length xs)  $\leq (2 \land \text{count-wc-queries } Rs$ sorter :: nat) and count-queries-ge: log 2 (fact (length xs))  $\leq$  real (count-wc-queries Rs sorter)  $\langle \text{proof} \rangle$ 

lemma ln-fact-bigo:  $(\lambda n. \ln (fact n) - (\ln (2 * pi * n) / 2 + n * \ln n - n)) \in O(\lambda n. 1 / n)$ 

and asymp-equiv-ln-fact [asymp-equiv-intros]:  $(\lambda n. \ln (fact n)) \sim [at-top] (\lambda n. n * ln n)$ 

 $\langle proof \rangle$ 

include asymp-equiv-syntax

 $\langle proof \rangle$ 

This leads to the following well-known Big-Omega bound on the number of comparisons that a general sorting algorithm has to make:

**corollary** count-queries-bigomega: **fixes** sorter :: nat  $\Rightarrow$  nat sorter **assumes** sorter:  $\land n \ R$ . linorder-on {..<n}  $R \Longrightarrow$ is-sorting  $R \ [0..<n]$  (eval-sorter  $R \ (sorter \ n)$ ) **defines**  $Rs \equiv \land n. \ \{R. \ linorder-on \ \{..<n\} \ R\}$  **shows**  $(\land n. \ count-wc-queries \ (Rs \ n) \ (sorter \ n)) \in \Omega(\land n. \ n \ s \ ln \ n)$  $\langle proof \rangle$ 

 $\mathbf{end}$
