Derandomization with Conditional Expectations

Emin Karayel

March 17, 2025

Abstract

The *Method of Conditional Expectations* [4] (sometimes also called "Method of Conditional Probabilities") is one of the prominent derandomization techniques. Given a randomized algorithm, it allows the construction of a deterministic algorithm with a result that matches the average-case quality of the randomized algorithm.

Using this technique, this entry starts with a simple example, an algorithm that obtains a cut that crosses at least half of the edges. This is a well-known approximate solution to the Max-Cut problem. It is followed by a more complex and interesting result: an algorithm that returns an independent set matching (or exceeding) the Caro-Wei bound [3]: $\frac{n}{d+1}$ where n is the vertex count and d is the average degree of the graph.

Both algorithms are efficient and deterministic, and follow from the derandomization of a probabilistic existence proof.

2 Method of Conditional Expectations: Large Cuts

The following is an example of the application of the method of conditional expectations [2, 1] to construct an approximation algorithm that finds a cut of an undirected graph cutting at least half of the edges. This is also the example that Vadhan [4, Section 3.4.2] uses to introduce the "Method of Conditional Expectations".

```
shows (\int C. of-bool (e \cap C \neq \{\} \land e - C \neq \{\}\}) \partial pmf-of-set \{C. L \subseteq C \land C \subseteq U\}) = ((if e \subseteq -U \cup L then of-bool(e \cap L \neq \{\} \land e \cap -U \neq \{\}\})::real else 1/2)) (is ?L = ?R) \langle proof \rangle
```

If every vertex is selected independently with probability $\frac{1}{2}$ into the cut, it is easy to deduce that an edge will be cut with probability $\frac{1}{2}$ as well. Thus the expected cut size will be *real graph-size* / 2.

```
lemma exp-cut-size: (\int C. real (cut\text{-size } C) \partial pmf\text{-of-set } (Pow \ V)) = real (card \ E) / 2 (is ?L = ?R) \langle proof \rangle
```

For the above it is easy to show that there exists a cut, cutting at least half of the edges.

```
lemma exists-cut: \exists C \subseteq V. real (cut-size C) \geq card E/2 \langle proof \rangle
```

end

However the above is just an existence proof, but it doesn't provide a method to construct such a cut efficiently. Here, we can apply the method of conditional expectations.

This works because, we can not only compute the expectation of the number of cut edges, when all vertices are chosen at random, but also conditional expectations, when some of the edges are fixed. The idea of the algorithm, is to choose the assignment of vertices into the cut based on which option maximizes the conditional expectation. The latter can be done incrementally for each vertex.

This results in the following efficient algorithm:

```
fun derandomized-max-cut :: 'a list \Rightarrow 'a set where derandomized-max-cut [] R - - = R | derandomized-max-cut (v\#vs) R B E = (if card {e \in E. \ v \in e \land e \cap R \neq \{\}} \geq card {e \in E. \ v \in e \land e \cap B \neq \{\}} then derandomized-max-cut vs R (B \cup \{v\}) E else derandomized-max-cut vs (R \cup \{v\}) E
```

context fin-sgraph begin

assumes $R \subseteq V B \subseteq V R \cap B = \{\}$

The term *cond-exp* is the conditional expectation, when some of the edges are selected into the cut, and some are selected to be outside the cut, while the remaining vertices are chosen randomly.

```
definition cond-exp where cond-exp R B = (\int C. real (cut-size C) \partial pmf-of-set \{C. R \subseteq C \land C \subseteq V - B\})
```

The following is the crucial property of conditional expectations, the average of choosing a vertex in/out is the same as not fixing that vertex. This means that at least one choice will not decrease the conditional expectation.

```
lemma cond-exp-split: assumes R \subseteq V B \subseteq V R \cap B = \{\} v \in V -R-B shows cond-exp R B = (cond-exp (R \cup \{v\})) B + cond-exp R (B \cup \{v\}))/2 (is ?L = ?R) proof) lemma cond-exp-cut-size:
```

```
shows cond\text{-}exp\ R\ B = real\ (card\ \{e\in E.\ e\cap R\neq \{\} \land e\cap B\neq \{\}\}) + real\ (card\ \{e\in E.\ e\cap V-R-B\neq \{\}\}) / 2 (is ?L = ?R) \langle proof \rangle Indeed the algorithm returns a cut with the promised approximation guarantee. theorem derandomized\text{-}max\text{-}cut: assumes vs \in permutations\text{-}of\text{-}set\ V defines C \equiv derandomized\text{-}max\text{-}cut\ vs\ \{\}\ \{\}\ E shows C \subseteq V\ 2 * cut\text{-}size\ C \ge card\ E \langle proof \rangle end
```

3 Method of Pessimistic Estimators: Independent Sets

A generalization of the the method of conditional expectations is the method of pessimistic estimators. Where the conditional expectations are conservatively approximated. The following example is such a case.

Starting with a probabilistic proof of Caro-Wei's theorem [1, Section: The Probabilistic Lens: Turán's theorem], this section constructs a deterministic algorithm that finds such a set.

```
{\bf theory}\ Derandomization-Conditional-Expectations-Independent-Set}\ {\bf imports}\ Derandomization-Conditional-Expectations-Cut}\ {\bf begin}
```

hide-fact (open) Henstock-Kurzweil-Integration.integral-sum

end

The following represents a greedy algorithm that walks through the vertices in a given order and adds it to a result set, if and only if it preserves independence of the set.

```
fun indep\text{-}set :: 'a \ list \Rightarrow 'a \ set \ set \Rightarrow 'a \ list
  where
    indep-set [] E = [] |
    indep-set (v \# vt) E = v \# indep-set (filter (\lambda w. \{v,w\} \notin E) vt) E
context fin-sgraph
begin
lemma indep-set-range: subseq (indep-set p E) p
\langle proof \rangle
lemma is-independent-set-insert:
  assumes is-independent-set A \ x \in V - environment A
  shows is-independent-set (insert x A)
  \langle proof \rangle
Correctness properties of indep-set:
theorem indep-set-correct:
  assumes distinct p set p \subseteq V
  shows distinct (indep-set p E) set (indep-set p E) \subseteq V is-independent-set (set (indep-set p E))
\langle proof \rangle
```

While for an individual call of *indep-set* it is not possible to derive a non-trivial bound on the size of the resulting independent set, it is possible to estimate its performance on

average, i.e., with respect to a random choice on the order it visits the vertices. This will be derived in the following:

```
definition is-first where is-first v p = prefix [v] (filter (\lambda y.\ y \in environment\ \{v\})\ p) lemma is-first-subseq: assumes is-first v p distinct p subseq q p v \in set q shows is-first v q \langle proof \rangle lemma is-first-imp-in-set: assumes is-first v p shows v \in set p \langle proof \rangle
```

Let us observe that a node, which comes first in the ordering of the vertices with respect to its neighbors, will definitely be in the independent set. (This is only a sufficient condition, but not a necessary condition.)

```
lemma set-indep-set:

assumes distinct p set p \subseteq V is-first v p

shows v \in set (indep-set p E)

\langle proof \rangle
```

Using the above we can establish the following lower-bound on the expected size of an independent set obtained by indep-set:

end

After establishing the above result, we may ask the question, whether there is a practical algorithm to find such a set. This is where the method of conditional expectations comes to stage.

We are tasked with finding an ordering of the vertices, for which the above algorithm would return an above-average independent set. This is possible, because we can compute the conditional expectation of

```
measure-pmf.expectation (pmf-of-set (permutations-of-set V)) (\lambda vs. \sum v \in V. of-bool (is-first vvs))
```

when we restrict to permutations starting with a given prefix. The latter term is a pessimistic estimator for the size of the independent set for the given ordering (as discussed above.)

It then is possible to obtain a deterministic algorithm that obtains an ordering by incrementally choosing vertices, that maximize the conditional expectation.

The resulting algorithm looks as follows:

```
function derandomized-indep-set :: 'a list \Rightarrow 'a list \Rightarrow 'a set set \Rightarrow 'a list
  where
    derandomized-indep-set [ p E = indep-set p E ]
    derandomized-indep-set (vh\#vt) p E = (
      let node-deg = (\lambda v. real (card \{e \in E. v \in e\}));
          is\text{-}indep = (\lambda v. \ list\text{-}all \ (\lambda w. \ \{v,w\} \notin E) \ p);
          env = (\lambda v. filter is-indep (v \# filter (\lambda w. \{v,w\} \in E) (vh \# vt)));
          cost = (\lambda v. \ (\sum w \leftarrow env \ v. \ 1 \ /(node-deg \ w+1)) - of-bool(is-indep \ v));
          w = arg\text{-}min\text{-}list cost (vh\#vt)
      in derandomized-indep-set (remove1 w (vh\#vt)) (p@[w]) E)
  \langle proof \rangle
termination
\langle proof \rangle
context fin-sgraph
begin
lemma is-first-append-1:
  assumes v \notin environment (set p)
  shows is-first v(p@q) = is-first vq
\langle proof \rangle
lemma is-first-append-2:
  assumes v \in environment (set p)
  shows is-first v(p@q) = is-first v(p
The conditional expectation of the pessimistic estimator for a given prefix of the ordering
of the vertices.
definition p-estimator where
  p-estimator p = (\int vs. (\sum v \in V. of\text{-}bool(is\text{-}first \ v \ vs)) \ \partial pmf\text{-}of\text{-}set \ (cond\text{-}perm \ V \ p))
lemma p-estimator-split:
  assumes V - set p \neq \{\}
  shows p-estimator p = (\sum v \in V - set \ p. \ p-estimator \ (p@[v])) \ / \ real \ (card \ (V - set \ p)) \ (is \ ?L = shows \ p-estimator \ p.
?R)
\langle proof \rangle
The fact that the pessimistic estimator can be computed efficiently is the reason we can
apply this method:
lemma p-estimator:
  assumes distinct p set p \subseteq V
  defines P \equiv \{v. \text{ is-first } v p\}
  defines R \equiv V - environment (set p)
  shows p-estimator p = card P + (\sum v \in R. \ 1/(degree \ v + 1::real))
    (is ?L = ?R)
\langle proof \rangle
lemma p-estimator-step:
  assumes distinct (p@[v]) set (p@[v]) \subseteq V
  shows p-estimator (p@[v]) - p-estimator p = of-bool(environment \{v\} \cap set \ p = \{\})
    -(\sum w \in environment \{v\} - environment(set p). 1 / (degree w+1::real))
\langle proof \rangle
```

```
lemma derandomized-indep-set-correct-aux:
   assumes p1@p2 \in permutations-of-set\ V
   shows distinct (derandomized-indep-set p1\ p2\ E) \land
        is-independent-set (set (derandomized-indep-set p1\ p2\ E))
\langle proof \rangle

lemma derandomized-indep-set-length-aux:
   assumes p1@p2 \in permutations-of-set\ V
   shows length (derandomized-indep-set p1\ p2\ E) \geq p-estimator p2\ \langle proof \rangle
```

The main result of this section the algorithm *derandomized-indep-set* obtains an independent set meeting the Caro-Wei bound in polynomial time.

```
theorem derandomized-indep-set:
    assumes p \in permutations\text{-}of\text{-}set\ V
    shows
    is-independent-set (set (derandomized-indep-set p\ []\ E))
    distinct (derandomized-indep-set p\ []\ E)
    length (derandomized-indep-set p\ []\ E) \geq (\sum v \in V.\ 1/\ (degree\ v+1))
    length (derandomized-indep-set p\ []\ E) \geq card\ V\ /\ (2*card\ E\ /\ card\ V\ +\ 1)
\langle proof \rangle
end
end
```
