Farkas' Lemma and Motzkin's Transposition $${\rm Theorem}^{*}$$

Ralph Bottesch Max W. Haslbeck René Thiemann

March 17, 2025

Abstract

We formalize a proof of Motzkin's transposition theorem and Farkas' lemma in Isabelle/HOL. Our proof is based on the formalization of the simplex algorithm which, given a set of linear constraints, either returns a satisfying assignment to the problem or detects unsatisfiability. By reusing facts about the simplex algorithm we show that a set of linear constraints is unsatisfiable if and only if there is a linear combination of the constraints which evaluates to a trivially unsatisfiable inequality.

1 Introduction

This formalization augments the existing formalization of the simplex algorithm [3, 5, 7]. Given a system of linear constraints, the simplex implementation in [3] produces either a satisfying assignment or a subset of the given constraints that is itself unsatisfiable. Here we prove some variants of Farkas' Lemma. In essence, it states that if a set of constraints is unsatisfiable, then there is a linear combination of these constraints that evaluates to an unsatisfiable inequality of the form $0 \leq c$, for some negative c.

Our proof of Farkas' Lemma [4, Cor. 7.1e] relies on the formalized simplex algorithm: Under the assumption that the algorithm has detected unsatisfiability, we show that there exist coefficients for the above-mentioned linear combination of the input constraints.

Since the formalized algorithm follows the structure of the simplexalgorithm by Dutertre and de Moura [2], it first goes through a number of preprocessing phases, before starting the simplex procedure in earnest. These are relevant for proving Farkas' Lemma. We distinguish four *layers* of the algorithm; at each layer, it operates on data that is a refinement of the data available at the previous layer.

- Layer 1. Data: the input a set of linear constraints with rational coefficients. These can be equalities or strict/non-strict inequalities. *Preprocessing*: Each equality is split into two non-strict inequalities, strict inequalities are replaced by non-strict inequalities involving δ -rationals.
- Layer 2. Data: a set of linear constraints that are non-strict inequalities with δ -rationals. Preprocessing: Linear constraints are simplified so that each constraint involves a single variable, by introducing socalled slack variables where necessary. The equations defining the slack variables are collected in a tableau. The constraints are normalized so that they are of the form $y \leq c$ or $y \geq c$ (these are called *atoms*).
- Layer 3. Data: A tableau and a set of atoms. Here the algorithm initializes the simplex algorithm.
- Layer 4. Data: A tableau, a set of atoms and an assignment of the variables. The simplex procedure is run.

At the point in the execution where the simplex algorithm detects unsatisfiability, we can directly obtain coefficients for the desired linear combination. However, these coefficients must then be propagated backwards through the different layers, where the constraints themselves have been modified, in order to obtain coefficients for a linear combination of *input* constraints. These propagation steps make up a large part of the formalized proof, since we must show, at each of the layers 1–3, that the existence of coefficients at the layer below translates into the existence of such coefficients for the current layer. This means, in particular, that we formulate and prove a version of Farkas' Lemma for each of the four layers, in terms of the data available at the respective level. The theorem we obtain at Layer 1 is actually a more general version of Farkas' lemma, in the sense that it allows for strict as well as non-strict inequalities, known as Motzkin's Transposition Theorem [4, Cor. 7.1k] or the Kuhn–Fourier Theorem [6, Thm. 1.1.9].

Since the implementation of the simplex algorithm in [3], which our work relies on, is restricted to systems of constraints over the rationals, this formalization is also subject to the same restriction.

2 Farkas Coefficients via the Simplex Algorithm of Duterte and de Moura

Let c_1, \ldots, c_n be a finite list of linear inequalities. Let C be a list of pairs (r_i, c_i) where r_i is a rational number. We say that C is a list of *Farkas* coefficients if the sum of all products $r_i \cdot c_i$ results in an inequality that is trivially unsatisfiable.

Farkas' Lemma states that a finite set of non-strict linear inequalities is unsatisfiable if and only if Farkas coefficients exist. We will prove this lemma with the help of the simplex algorithm of Dutertre and de Moura's.

Note that the simplex implementation works on four layers, and we will formulate and prove a variant of Farkas' Lemma for each of these layers.

theory Farkas imports Simplex.Simplex begin

2.1 Linear Inequalities

Both Farkas' Lemma and Motzkin's Transposition Theorem require linear combinations of inequalities. To this end we define one type that permits strict and non-strict inequalities which are always of the form "polynomial R constant" where R is either \leq or <. On this type we can then define a commutative monoid.

A type for the two relations: less-or-equal and less-than.

datatype $le-rel = Leq-Rel \mid Lt-Rel$

2.2 Farkas' Lemma on Layer 4

On layer 4 the algorithm works on a state containing a tableau, atoms (or bounds), an assignment and a satisfiability flag. Only non-strict inequalities appear at this level. In order to even state a variant of Farkas' Lemma on layer 4, we need conversions from atoms to non-strict constraints and then further to linear inequalities of type *le-constraint*. The latter conversion is a partial operation, since non-strict constraints of type *ns-constraint* permit

greater-or-equal constraints, whereas *le-constraint* allows only less-or-equal.

The advantage of first going via *ns-constraint* is that this type permits a multiplication with arbitrary rational numbers (the direction of the inequality must be flipped when multiplying by a negative number, which is not possible with *le-constraint*).

instantiation *ns-constraint* :: (*scaleRat*) *scaleRat* begin

We say that C is a list of Farkas coefficients for a given tableau t and atom set as, if it is a list of pairs (r, a) such that $a \in as$, r is non-zero, $r \cdot a$ is a 'less-than-or-equal'-constraint, and the linear combination of inequalities must result in an inequality of the form $p \leq c$, where c < 0 and $t \models p = 0$.

 ${\bf definition} \ fark as {\it -coefficients-atoms-tableau} \ {\bf where}$

 $\begin{aligned} & farkas\text{-}coefficients\text{-}atoms\text{-}tableau \ (as :: 'a :: lrv \ atom \ set) \ t \ C = (\exists \ p \ c. \\ & (\forall (r,a) \in set \ C. \ a \in as \land is\text{-}leq\text{-}ns \ (r \ *R \ nsc\text{-}of\text{-}atom \ a) \land r \neq 0) \land \\ & (\sum (r,a) \leftarrow C. \ lec\text{-}of\text{-}nsc \ (r \ *R \ nsc\text{-}of\text{-}atom \ a)) = Leqc \ p \ c \land \\ & c < 0 \land \\ & (\forall \ v :: 'a \ valuation. \ v \models_t \ t \longrightarrow (p\{\!\{v\}\!\} = 0))) \end{aligned}$

We first prove that if the check-function detects a conflict, then Farkas coefficients do exist for the tableau and atom set for which the conflict is detected.

2.3 Farkas' Lemma on Layer 3

There is only a small difference between layers 3 and 4, namely that there is no simplex algorithm (*assert-all-state*) on layer 3, but just a tableau and atoms.

Hence, one task is to link the unsatisfiability flag on layer 4 with unsatisfiability of the original tableau and atoms (layer 3). This can be done via the existing soundness results of the simplex algorithm. Moreover, we give an easy proof that the existence of Farkas coefficients for a tableau and set of atoms implies unsatisfiability.

```
end
```

```
lemma farkas-coefficients-atoms-tableau-unsat:

assumes farkas-coefficients-atoms-tableau as t C

2.4 Farkas' Lemma on Layer 2

The main difference between layers 2 and 3 is the introduction of slack-variables in layer 3 via the preprocess-function. Our task here is to show that Farkas coefficients at layer 3 (where slack-variables are used) can be converted into Farkas coefficients for layer 2 (before the preprocessing).

We also need to adapt the previos notion of Farkas coefficients, which

was used in farkas-coefficients-atoms-tableau, for layer 2. At layer 3, Farkas coefficients are the coefficients in a linear combination of atoms that evaluates to an inequality of the form $p \leq c$, where p is a linear polynomial, c < 0, and $t \models p = 0$ holds. At layer 2, the atoms are replaced by non-strict constraints where the left-hand side is a polynomial in the original variables, but the corresponding linear combination (with Farkas coefficients) evaluates directly to the inequality $0 \leq c$, with c < 0. The implication $t \models p = 0$ is no longer possible in this layer, since there is no tableau t, nor is it needed, since p is 0. Thus, the statement defining Farkas coefficients must be changed accordingly.

definition farkas-coefficients-ns where

farkas-coefficients-ns ns $C = (\exists c.$ $(\forall (r, n) \in set C. n \in ns \land is-leq-ns (r * R n) \land r \neq 0) \land$ $(\sum (r, n) \leftarrow C. lec-of-nsc (r * R n)) = Leqc \ 0 \ c \land$ c < 0)

The easy part is to prove that Farkas coefficients imply unsatisfiability.

```
lemma farkas-coefficients-ns-unsat:
 assumes farkas-coefficients-ns ns C
 shows \nexists v. v \models_{nss} ns
proof
  assume \exists v. v \models_{nss} ns

  then show False using cltz
   by (metis leD satisfiable-le-constraint.simps valuate-zero rel-of.simps(1))
qed
```

In order to eliminate the need for a tableau, we require the notion of an arbitrary substitution on polynomials, where all variables can be replaced at once. The existing simplex formalization provides only a function to replace one variable at a time.

definition subst-poly :: $(var \Rightarrow linear-poly) \Rightarrow linear-poly \Rightarrow linear-poly$ where

subst-poly $\sigma \ p = (\sum x \in vars \ p. \ coeff \ p \ x * R \ \sigma \ x)$

lemma subst-poly-0[simp]: subst-poly σ 0 = 0 unfolding subst-poly-def by simp

lemma subst-poly-add: subst-poly σ (p + q) = subst-poly σ p + subst-poly σ qby (rule linear-poly-eqI, unfold valuate-add valuate-subst-poly, simp)

fun subst-poly-lec :: $(var \Rightarrow linear-poly) \Rightarrow 'a \ le-constraint \Rightarrow 'a \ le-constraint$ where

subst-poly-lec σ (Le-Constraint rel p c) = Le-Constraint rel (subst-poly σ p) c

lemma subst-poly-lec-0[simp]: subst-poly-lec σ 0 = 0 unfolding zero-le-constraint-def by simp

lemma subst-poly-lec-add: subst-poly-lec σ (c1 + c2) = subst-poly-lec σ c1 + subst-poly-lec σ c2

by (cases c1; cases c2, auto simp: subst-poly-add)

lemma subst-poly-lec-sum-list: subst-poly-lec σ (sum-list ps) = sum-list (map (subst-poly-lec σ) ps)

by (*induct ps*, *auto simp*: *subst-poly-lec-add*)

lemma subst-poly-lp-monom[simp]: subst-poly σ (lp-monom r x) = $r * R \sigma x$ unfolding subst-poly-def by (simp add: vars-lp-monom)

lemma subst-poly-scaleRat: subst-poly σ (r * R p) = r * R (subst-poly σ p) **by** (rule linear-poly-eqI, unfold valuate-scaleRat valuate-subst-poly, simp)

We need several auxiliary properties of the preprocess-function which are not present in the simplex formalization.

lemma Tableau-is-monom-preprocess':

assumes $(x, p) \in set$ (Tableau (preprocess' cs start)) shows \neg is-monom p using assms by(induction cs start rule: preprocess'.induct) (auto simp add: Let-def split: if-splits option.splits)

lemma preprocess'-atoms-to-constraints': **assumes** preprocess' cs start = S **shows** set (Atoms S) \subseteq {(i,qdelta-constraint-to-atom c v) | i c v. (i,c) \in set cs \land

 $(\neg is-monom (poly c) \longrightarrow Poly-Mapping S (poly c) = Some v)\}$ unfolding assms(1)[symmetric]

by (*induct cs start rule: preprocess'.induct, auto simp: Let-def split: option.splits, force+*)

lemma monom-of-atom-coeff:

assumes is-monom (poly ns) a = qdelta-constraint-to-atom ns v shows (monom-coeff (poly ns)) *R nsc-of-atom a = nsusing assms is-monom-monom-coeff-not-zero by(cases a; cases ns) (auto split: atom.split ns-constraint.split simp add: monom-poly-assemble field-simps)

The next lemma provides the functionality that is required to convert an atom back to a non-strict constraint, i.e., it is a kind of inverse of the preprocess-function.

2.5 Farkas' Lemma on Layer 1

The main difference of layers 1 and 2 is the restriction to non-strict constraints via delta-rationals. Since we now work with another constraint type, *constraint*, we again need translations into linear inequalities of type *le-constraint*. Moreover, we also need to define scaling of constraints where flipping the comparison sign may be required.

fun is-le :: constraint \Rightarrow bool where is-le (LT - -) = True | is-le (LEQ - -) = True | is-le - = False

fun lec-of-constraint **where** lec-of-constraint (LEQ p c) = (Le-Constraint Leq-Rel p c) | lec-of-constraint (LT p c) = (Le-Constraint Lt-Rel p c)

lemma lec-of-constraint: **assumes** is-le c **shows** $(v \models_{le} (lec-of-constraint c)) \longleftrightarrow (v \models_c c)$ **using** assms **by** (cases c, auto)

instantiation constraint :: scaleRat begin

fun scaleRat-constraint :: rat \Rightarrow constraint \Rightarrow constraint where scaleRat-constraint r cc = (if r = 0 then LEQ 0 0 else (case cc of LEQ p c \Rightarrow (if (r < 0) then GEQ (r *R p) (r *R c) else LEQ (r *R p) (r *R c)) | LT p c \Rightarrow (if (r < 0) then GT (r *R p) (r *R c) else LT (r *R p) (r *R c)) | GEQ p c \Rightarrow (if (r > 0) then GEQ (r *R p) (r *R c) else LEQ (r *R p) (r *R c)) | GT p c \Rightarrow (if (r > 0) then GT (r *R p) (r *R c) else LT (r *R p) (r *R c)) | EQ p c \Rightarrow LEQ (r *R p) (r *R c) else LT (r *R p) (r *R c)) | EQ p c \Rightarrow LEQ (r *R p) (r *R c) — We do not keep equality, since the aim is to convert the scaled constraints into inequalities, which will then be summed up.))

instance .. end

lemma sat-scale-rat: **assumes** $(v :: rat valuation) \models_c c$ **shows** $v \models_c (r * R c)$ **proof** – **have** $r < 0 \lor r = 0 \lor r > 0$ **by** auto **then show** ?thesis **using** assms **by** (cases c, auto simp: right-diff-distrib valuate-minus valuate-scaleRat scaleRat-leq1 scaleRat-leq2 valuate-zero) **qed** In the following definition of Farkas coefficients (for layer 1), the main difference to *farkas-coefficients-ns* is that the linear combination evaluates either to a strict inequality where the constant must be non-positive, or to a non-strict inequality where the constant must be negative.

 ${\bf definition} \ farkas\text{-}coefficients \ {\bf where}$

 $\begin{array}{l} \text{farkas-coefficients cs } C = (\exists \ d \ rel. \\ (\forall \ (r,c) \in set \ C. \ c \in cs \land is-le \ (r \ *R \ c) \land r \neq 0) \land \\ (\sum \ (r,c) \leftarrow C. \ lec\text{-of-constraint} \ (r \ *R \ c)) = Le\text{-Constraint} \ rel \ 0 \ d \land \\ (rel = Leq\text{-Rel} \land d < 0 \lor rel = Lt\text{-Rel} \land d \leq 0)) \end{array}$

Again, the existence Farkas coefficients immediately implies unsatisfiability.

```
lemma farkas-coefficients-unsat:
 assumes farkas-coefficients cs C
 shows \nexists v. v \models_{cs} cs
proof
  assume \exists v. v \models_{cs} cs
  then obtain v where *: v \models_{cs} cs by auto
  obtain d rel where
    isleq: (\forall (r,c) \in set \ C. \ c \in cs \land is-le \ (r \ast R \ c) \land r \neq 0) and
   leq: (\sum (r,c) \leftarrow C. lec-of-constraint (r \ast R c)) = Le-Constraint rel 0 d and
  choice: rel = Lt - Rel \land d \le 0 \lor rel = Leq - Rel \land d < 0 using assms farkas-coefficients-def

   by (rule satisfies-sumlist-le-constraints, insert v, auto)
  then show False using choice
   by (cases rel, auto simp: valuate-zero)
qed
```

Now follows the difficult implication. The major part is proving that the translation *constraint-to-qdelta-constraint* preserves the existence of Farkas coefficients via pointwise compatibility of the sum. Here, compatibility links a strict or non-strict inequality from the input constraint to a translated non-strict inequality over delta-rationals.

${\bf fun} \ compatible\mathchar`cs \ {\bf where}$

compatible-cs (Le-Constraint Leq-Rel p c) (Le-Constraint Leq-Rel q d) = (q = p $\land d = QDelta \ c \ 0$) $\mid compatible-cs$ (Le-Constraint Lt-Rel p c) (Le-Constraint Leq-Rel q d) = ($q = p \land qdfst \ d = c$) | compatible-cs - - = False

3 Corollaries from the Literature

In this section, we convert the previous variations of Farkas' Lemma into more well-known forms of this result. Moreover, instead of referring to the various constraint types of the simplex formalization, we now speak solely about constraints of type *le-constraint*.

3.1 Farkas' Lemma on Delta-Rationals

We start with Lemma 2 of [1], a variant of Farkas' Lemma for delta-rationals. To be more precise, it states that a set of non-strict inequalities over delta-rationals is unsatisfiable if and only if there is a linear combination of the inequalities that results in a trivial unsatisfiable constraint 0 < const for some negative constant *const*. We can easily prove this statement via the lemma *farkas-coefficients-ns* and some conversions between the different constraint types.

```

3.2 Motzkin's Transposition Theorem or the Kuhn-Fourier Theorem

Next, we prove a generalization of Farkas' Lemma that permits arbitrary combinations of strict and non-strict inequalities: Motzkin's Transposition Theorem which is also known as the Kuhn–Fourier Theorem.

The proof is mainly based on the lemma *farkas-coefficients*, again requiring conversions between constraint types.

theorem Motzkin's-transposition-theorem: **fixes** cs :: rat le-constraint set assumes fin: finite cs

shows $(\nexists v. \forall c \in cs. v \models_{le} c) \leftrightarrow$ $(\exists C const rel. (\forall (r, c) \in set C. r > 0 \land c \in cs))$ $\wedge (\sum (r,c) \leftarrow C.$ Le-Constraint (lec-rel c) (r * R lec-poly c) (r * R lec-const)c))= Le-Constraint rel 0 const $\wedge (rel = Leq-Rel \wedge const < 0 \lor rel = Lt-Rel \wedge const \le 0))$ (**is** ?lhs = ?rhs)proof let ?to-cs = λ c. 4 Unsatisfiability over the Reals

By using Farkas' Lemma we prove that a finite set of linear rational inequalities is satisfiable over the rational numbers if and only if it is satisfiable over the real numbers. Hence, the simplex algorithm either gives a rational solution or shows unsatisfiability over the real numbers.

simplex $cs = Sat v \Longrightarrow \langle v \rangle \models_{cs} set cs$ — satisfying assignment over the rationals **proof** (intro simplex(1)[unfolded rat-real-conversion[OF finite-set]]) **assume** unsat: simplex cs = Inl I **have** finite { $cs ! i | i. i \in set I$ } **by** auto from simplex(2)[OF unsat, unfolded rat-real-conversion[OF this]] **show** set $I \subseteq \{0...<$ length $cs\} \land \neg (\exists v. v \models_{rcs} \{cs ! i | i. i \in set I\})$ $\land (\forall J \subseteq set I. \exists v. v \models_{cs} \{cs ! i | i. i \in J\})$ **by** auto **and** (insert simplex(3) auto)

 $\mathbf{qed} \ (insert \ simplex(3), \ auto)$

Define notion of minimal unsat core over the reals: the subset has to be unsat over the reals, and every proper subset has to be satisfiable over the rational numbers.

definition minimal-unsat-core-real :: 'i set \Rightarrow 'i i-constraint list \Rightarrow bool where minimal-unsat-core-real I ics = ((I \subseteq fst ' set ics) \land (\neg (\exists v. (I,v) \models_{rics} set ics))

 $\land (distinct\text{-}indices \ ics \longrightarrow (\forall \ J. \ J \subset I \longrightarrow (\exists \ v. \ (J,v) \models_{ics} set \ ics))))$

Because of equi-satisfiability the two notions of minimal unsat cores coincide.

lemma minimal-unsat-core-real-conv: minimal-unsat-core-real I ics = minimal-unsat-core I ics

proof

```
show minimal-unsat-core-real I ics ⇒ minimal-unsat-core I ics
unfolding minimal-unsat-core-real-def minimal-unsat-core-def
using of-rat-val-constraint by simp metis
next
assume minimal-unsat-core I ics
thus minimal-unsat-core-real I ics
unfolding minimal-unsat-core-real-def minimal-unsat-core-def
using rat-real-conversion[of Simplex.restrict-to I (set ics)]
by auto
qed
```

Easy consequence: The incremental simplex algorithm is also sound wrt. minimal-unsat-cores over the reals.

```
lemmas incremental-simplex-real =
    init-simplex
    assert-simplex-ok
    assert-all-simplex-ok
    assert-all-simplex-unsat[folded minimal-unsat-core-real-conv]
    check-simplex-ok
    check-simplex-ok
    check-simplex-unsat[folded minimal-unsat-core-real-conv]
    solution-simplex
    backtrack-simplex
    checked-invariant-simplex
```
