IMP2 — Simple Program Verification in Isabelle/HOL

Peter Lammich   Simon Wimmer

May 26, 2024

Abstract

IMP2 is a simple imperative language together with Isabelle tooling to create a program verification environment in Isabelle/HOL. The tools include a C-like syntax, a verification condition generator, and Isabelle commands for the specification of programs. The framework is modular, i.e., it allows easy reuse of already proved programs within larger programs.

This entry comes with a quickstart guide and a large collection of examples, spanning basic algorithms with simple proofs to more advanced algorithms and proof techniques like data refinement. Some highlights from the examples are: Bisection Square Root, Extended Euclid, Exponentiation by Squaring, Binary Search, Insertion Sort, Quicksort, Depth First Search.

The abstract syntax and semantics are very simple and well-documented. They are suitable to be used in a course, as extension to the IMP language which comes with the Isabelle distribution.

While this entry is limited to a simple imperative language, the ideas could be extended to more sophisticated languages.

Contents

1 Abstract Syntax of IMP2

theory *Syntax*
imports *Main*
begin

We define the abstract syntax of the IMP2 language, and a minimal concrete syntax for direct use in terms.

1.1 Primitives

Variable and procedure names are strings.

type-synonym *vname* = *string*
type-synonym *pname* = *string*

The variable names are partitioned into local and global variables.

fun *is-global* :: *vname* ⇒ *bool* **where**
is-global [] ⟷ *True*
| *is-global* (*CHR* ''*G*''#-) ⟷ *True*
| *is-global* - ⟷ *False*

abbreviation *is-local* *a* ≡ ¬*is-global* *a*

Primitive values are integers, and values are arrays modeled as functions from integers to primitive values.

Note that values and primitive values are usually part of the semantics, however, as they occur as literals in the abstract syntax, we already define them here.

type-synonym *pval* = *int*
type-synonym *val* = *int* ⇒ *pval*

1.2 Arithmetic Expressions

Arithmetic expressions consist of constants, indexed array variables, and unary and binary operations. The operations are modeled by reflecting arbitrary functions into the abstract syntax.

datatype *aexp* =
N int

| *Vidx vname aexp*
| *Unop int* ⇒ *int aexp*
| *Binop int* ⇒ *int* ⇒ *int aexp aexp*

1.3 Boolean Expressions

Boolean expressions consist of constants, the not operation, binary connectives, and comparison operations. Binary connectives and comparison operations are modeled by reflecting arbitrary functions into the abstract syntax. The not operation is the only meaningful unary Boolean operation, so we chose to model it explicitly instead of reflecting and unary Boolean function.

datatype *bexp* =
Bc bool
| *Not bexp*
| *BBinop bool* ⇒ *bool* ⇒ *bool bexp bexp*
| *Cmpop int* ⇒ *int* ⇒ *bool aexp aexp*

1.4 Commands

The commands can roughly be put into five categories:

Skip The no-op command

Assignment commands Commands to assign the value of an arithmetic expression, copy or clear arrays, and a command to simultaneously assign all local variables, which is only used internally to simplify the definition of a small-step semantics.

Block commands The standard sequential composition, if-then-else, and while commands, and a scope command which executes a command with a fresh set of local variables.

Procedure commands Procedure call, and a procedure scope command, which executes a command in a specified procedure environment. Similar to the scope command, which introduces new local variables, and thus limits the effect of variable manipulations to the content of the command, the procedure scope command introduces new procedures, and limits the validity of their names to the content of the command. This greatly simplifies modular definition of programs, as procedure names can be used locally.

datatype
com =
SKIP — No-op

— Assignment
| *AssignIdx vname aexp aexp* — Assign to index in array
| *ArrayCpy vname vname* — Copy whole array
| *ArrayClear vname* — Clear array
| *Assign-Locals vname* $\Rightarrow$ *val* — Internal: Assign all local variables simultaneously

— Block
| *Seq com com* — Sequential composition
| *If bexp com com* — Conditional
| *While bexp com* — While-loop
| *Scope com* — Local variable scope

— Procedure
| *PCall pname* — Procedure call
| *PScope pname* $\rightharpoonup$ *com com* — Procedure scope

1.4.1 Minimal Concrete Syntax

The commands come with a minimal concrete syntax, which is compatible to the syntax of *IMP*.

notation *AssignIdx* (-[-] ::= - [*1000*, *0*, *61*] *61*)
notation *ArrayCpy* (-[] ::= - [*1000*, *1000*] *61*)
notation *ArrayClear* (*CLEAR* -[] [*1000*] *61*)

notation *Seq* (-;;/ - [*61*, *60*] *60*)
notation *If* ((*IF* -/ *THEN* -/ *ELSE* -) [*0*, *0*, *61*] *61*)
notation *While* ((*WHILE* -/ *DO* -) [*0*, *61*] *61*)
notation *Scope* (*SCOPE* - [*61*] *61*)

1.5 Program

type-synonym *program* = *pname* $\rightharpoonup$ *com*

1.6 Default Array Index

We define abbreviations to make arrays look like plain integer variables: Without explicitly specifying an array index, the index *0* will be used automatically.

abbreviation *V x* $\equiv$ *Vidx x* (*N 0*)
abbreviation *Assign* (- ::= - [*1000*, *61*] *61*)
where *x* ::= *a* $\equiv$ (*x*[*N 0*] ::= *a*)

end

2 Semantics of IMP

```
theory Semantics
imports Syntax HOL−Eisbach.Eisbach-Tools
begin
```

2.1 State

The state maps variable names to values

```
type-synonym state = vname ⇒ val
```

We introduce some syntax for the null state, and a state where only certain variables are set.

```
definition null-state (<>) where
  null-state ≡ λx. λi. 0
syntax
  -State :: updbinds => 'a (<->)
translations
  -State ms == -Update <> ms
  -State (-updbinds b bs) <= -Update (-State b) bs
```

2.1.1 State Combination

The state combination operator constructs a state by taking the local variables from one state, and the globals from another state.

```
definition combine-states :: state ⇒ state ⇒ state (<-|-> [0,0] 1000)
  where <s|t> n = (if is-local n then s n else t n)
```

We prove some basic facts.

Note that we use Isabelle's context command to locally declare the definition of *combine-states* as simp lemma, such that it is unfolded automatically.

```
context notes [simp] = combine-states-def begin

lemma combine-collapse: <s|s> = s by auto

lemma combine-nest:
  <s|<s'|t>> = <s|t>
  <<s|t'>|t> = <s|t>
  by auto

lemma combine-query:
  is-local x ⟹ <s|t> x = s x
  is-global x ⟹ <s|t> x = t x
  by auto

lemma combine-upd:
```

is-local x ⟹ <s|t>(x:=v) = <s(x:=v)|t>
is-global x ⟹ <s|t>(x:=v) = <s|t(x:=v)>
by *auto*

lemma *combine-cases*[*cases type*]:
obtains *l g* **where** *s* = <l|g>
by (*fastforce*)

end

2.2 Arithmetic Expressions

The evaluation of arithmetic expressions is straightforward.

fun *aval* :: *aexp* ⇒ *state* ⇒ *pval* **where**
aval (*N n*) *s* = *n*
| *aval* (*Vidx x i*) *s* = *s x* (*aval i s*)
| *aval* (*Unop f* a_1) *s* = *f* (*aval* a_1 *s*)
| *aval* (*Binop f* a_1 a_2) *s* = *f* (*aval* a_1 *s*) (*aval* a_2 *s*)

2.3 Boolean Expressions

The evaluation of Boolean expressions is straightforward.

fun *bval* :: *bexp* ⇒ *state* ⇒ *bool* **where**
bval (*Bc v*) *s* = *v*
| *bval* (*Not b*) *s* = (¬ *bval b s*)
| *bval* (*BBinop f* b_1 b_2) *s* = *f* (*bval* b_1 *s*) (*bval* b_2 *s*)
| *bval* (*Cmpop f* a_1 a_2) *s* = *f* (*aval* a_1 *s*) (*aval* a_2 *s*)

2.4 Big-Step Semantics

The big-step semantics is a relation from commands and start states to end states, such that there is a terminating execution.

If there is no such execution, no end state will be related to the command and start state. This either means that the program does not terminate, or gets stuck because it tries to call an undefined procedure.

The inference rules of the big-step semantics are pretty straightforward.

inductive *big-step* :: *program* ⇒ *com* × *state* ⇒ *state* ⇒ *bool*
(-: - ⇒ - [*1000*,*55*,*55*] *55*)
where
— No-Op
Skip: π:(*SKIP*,*s*) ⇒ *s*

by (*auto intro*!: *equivI*)

lemma *sim-while-cong-aux*:

$[\![\pi$:(*WHILE* b *DO* c,s) $\Rightarrow$ t; *bval* b = *bval* b'; $c \sim c'$ $]\!] \Longrightarrow \pi$:(*WHILE* b' *DO* c',s) $\Rightarrow$ t
by(*induction WHILE b DO c s t arbitrary*: *b c rule*: *big-step-induct*) *auto*

lemma *sim-while-cong*: *bval* b = *bval* $b' \Longrightarrow c \sim c' \Longrightarrow$ *WHILE* b *DO* $c \sim$ *WHILE* b' *DO* c'
using *equiv-c-def sim-while-cong-aux* **by** *auto*

2.6 Execution is Deterministic

This proof is automatic.

theorem *big-step-determ*: $[\![$ π:(c,s) $\Rightarrow$ t; π:(c,s) $\Rightarrow$ u $]\!] \Longrightarrow u = t$
proof (*induction arbitrary*: *u rule*: *big-step.induct*)
case (*WhileTrue* b s_1 c s_2 s_3)
then show *?case* **by** *blast*
qed *fastforce+*

2.7 Small-Step Semantics

The small step semantics is defined by a step function on a pair of command and state. Intuitively, the command is the remaining part of the program that still has to be executed. The step function is defined to stutter if the command is *SKIP*.

Moreover, the step function is explicitly partial, returning *None* on error, i.e., on an undefined procedure call.

Most steps are straightforward. For a sequential composition, steps are performed on the first command, until it has been reduced to *SKIP*, then the sequential composition is reduced to the second command.

A while command is reduced by unfolding the loop once.

A scope command is reduced to the inner command, followed by an *Assign-Locals* command to restore the original local variables.

A procedure scope command is reduced by performing a step in the inner command, with the new procedure environment, until the inner command has been reduced to *SKIP*. Then, the whole command is reduced to *SKIP*.

fun *small-step* :: *program* $\Rightarrow$ *com* $\times$ *state* $\rightharpoonup$ *com* $\times$ *state* **where**
small-step π (x[i]::=a,s) = *Some* (*SKIP*, s(x := (s x)(*aval* i s := *aval* a s)))
| *small-step* π (x[]::=y,s) = *Some* (*SKIP*, s(x := s y))
| *small-step* π (*CLEAR* x[],s) = *Some* (*SKIP*, s(x := (λ-. *0*)))
| *small-step* π (*Assign-Locals* l,s) = *Some* (*SKIP*,<l|s>)
| *small-step* π (*SKIP*;;c,s) = *Some* (c,s)

| *small-step* π (c_1;;c_2,s) = (*case small-step* π (c_1,s) *of Some* (c_1',s') $\Rightarrow$ *Some* (c_1';;c_2,s') | - $\Rightarrow$ *None*)
| *small-step* π (*IF b THEN* c_1 *ELSE* c_2,s) = *Some* (*if bval b s then* (c_1,s) *else* (c_2,s))
| *small-step* π (*SCOPE c, s*) = *Some* (*c*;;*Assign-Locals s*, $<<>|s>$)
| *small-step* π (*WHILE b DO c*,*s*) = *Some* (*IF b THEN c*;;*WHILE b DO c ELSE SKIP*, *s*)
| *small-step* π (*PCall p*, *s*) = (*case* π *p of Some c* $\Rightarrow$ *Some* (*c*, *s*) | - $\Rightarrow$ *None*)
| *small-step* π (*PScope* π' *SKIP*, *s*) = *Some* (*SKIP*,*s*)
| *small-step* π (*PScope* π' *c*, *s*) = (*case small-step* π' (*c*,*s*) *of Some* (c',s') $\Rightarrow$ *Some* (*PScope* π' c', s') | - $\Rightarrow$ *None*)
| *small-step* π (*SKIP*,*s*) = *Some* (*SKIP*,*s*)

We define the reflexive transitive closure of the step function.

  by (*auto simp*: *big-eq-small small-steps-determ*)

2.8 Weakest Precondition

The following definitions are made wrt. a fixed program π, which becomes the first parameter of the defined constants when the context is left.

context
  fixes π :: *program*
begin

Weakest precondition: c terminates with a state that satisfies Q, when started from s.

  definition *wp c Q s* $\equiv$ $\exists$*t*. π: (*c*,*s*) $\Rightarrow$ *t* $\wedge$ *Q t*
   — Note that this definition exploits that the semantics is deterministic! In general, we must ensure absence of infinite executions

Weakest liberal precondition: If c terminates when started from s, the new state satisfies Q.

definition $wlp\ c\ Q\ s \equiv \forall\, t.\ \pi{:}(c,s) \Rightarrow t \longrightarrow Q\ t$

2.8.1 Basic Properties

context
notes $[abs\text{-}def,simp] = wp\text{-}def\ wlp\text{-}def$
begin

context fixes π :: *program* **begin**
definition $sp\ P\ c\ t \equiv \exists\, s.\ P\ s \wedge \pi{:}\ (c,s) \Rightarrow t$

context notes [*simp*] = *sp-def*[*abs-def*] **begin**

Intuition: There exists an old value *vx* for the assigned variable

lemma *sp-arraycpy-eq*: $sp\ P\ (x[]::=y)\ t \longleftrightarrow (\exists\, vx.\ let\ s = t(x:=vx)\ in\ t\ x = s\ y \wedge P\ s)$
apply (*auto simp*: *big-step-simps*)
apply (*intro exI conjI*, *assumption*, *auto*) []
apply (*intro exI conjI*, *assumption*, *auto*) []
done

Version with renaming of assigned variable

lemma *sp-arraycpy-eq'*: $sp\ P\ (x[]::=y)\ t \longleftrightarrow t\ x = t\ y \wedge (\exists\, vx.\ P\ (t(x:=vx, y:=t\ x)))$
apply (*auto simp*: *big-step-simps*)
apply (*metis fun-upd-triv*)
apply (*intro exI conjI*, *assumption*)
apply *auto*
done

lemma *sp-skip-eq*: $sp\ P\ SKIP\ t \longleftrightarrow P\ t$ **by** *auto*
lemma *sp-seq-eq*: $sp\ P\ (c_1;;c_2)\ t \longleftrightarrow sp\ (sp\ P\ c_1)\ c_2\ t$ **by** *auto*

end
end

2.12 Hoare-Triples

A Hoare-triple summarizes the precondition, command, and postcondition.

definition *HT*
where $HT\ \pi\ P\ c\ Q \equiv (\forall\, s_0.\ P\ s_0 \longrightarrow wp\ \pi\ c\ (Q\ s_0)\ s_0)$

definition *HT-partial*
where $HT\text{-}partial\ \pi\ P\ c\ Q \equiv (\forall\, s_0.\ P\ s_0 \longrightarrow wlp\ \pi\ c\ (Q\ s_0)\ s_0)$

Consequence rule—strengthen the precondition, weaken the postcondition.

lemma *HT-conseq*:
assumes $HT\ \pi\ P\ c\ Q$
assumes $\bigwedge s.\ P'\ s \Longrightarrow P\ s$
assumes $\bigwedge s_0\ s.\ [\![P\ s_0;\ P'\ s_0;\ Q\ s_0\ s\ ]\!] \Longrightarrow Q'\ s_0\ s$
shows $HT\ \pi\ P'\ c\ Q'$
using *assms* **unfolding** *HT-def* **by** (*blast intro*: *wp-conseq*)

lemma *HT-partial-conseq*:
assumes $HT\text{-}partial\ \pi\ P\ c\ Q$
assumes $\bigwedge s.\ P'\ s \Longrightarrow P\ s$
assumes $\bigwedge s_0\ s.\ [\![P\ s_0;\ P'\ s_0;\ Q\ s_0\ s\ ]\!] \Longrightarrow Q'\ s_0\ s$
shows $HT\text{-}partial\ \pi\ P'\ c\ Q'$
using *assms* **unfolding** *HT-partial-def* **by** (*blast intro*: *wlp-conseq*)

Simple rule for presentation in lecture: Use a Hoare-triple during VCG.

lemma *wp-modularity-rule*:
$[\![HT\ \pi\ P\ c\ Q;\ P\ s;\ (\bigwedge s'.\ Q\ s\ s' \Longrightarrow Q'\ s')]\!] \Longrightarrow wp\ \pi\ c\ Q'\ s$
unfolding *HT-def*
by (*blast intro*: *wp-conseq*)

2.12.1 Sets of Hoare-Triples

type-synonym *htset* = ((*state* ⇒ *bool*) × *com* × (*state* ⇒ *state* ⇒ *bool*)) *set*

definition *HTset* π $\Theta \equiv \forall (P,c,Q){\in}\Theta.\ HT\ \pi\ P\ c\ Q$

definition *HTset-r* $r\ \pi\ \Theta \equiv \forall (P,c,Q){\in}\Theta.\ HT\ \pi\ (\lambda s.\ r\ c\ s \wedge P\ s)\ c\ Q$

2.12.2 Deriving Parameter Frame Adjustment Rules

The following rules can be used to derive Hoare-triples when adding prologue and epilogue code, and wrapping the command into a scope.

This will be used to implement the local variables and parameter passing protocol of procedures.

Intuition: New precondition is weakest one we need to ensure P after prologue.

lemma *adjust-prologue*:
  assumes *HT* π *P body Q*
  shows *HT* π (*wp* π *prologue P*) (*prologue*;;*body*) (λs_0 *s*. *wp* π *prologue* (λs_0. *Q* s_0 *s*) s_0)
  using *assms*
  unfolding *HT-def*
  apply (*auto simp*: *wp-eq*)
  using *wp-def* **by** *fastforce*

Intuition: New postcondition is strongest one we can get from Q after epilogue.

We have to be careful with non-terminating epilogue, though!

lemma *adjust-epilogue*:
  assumes *HT* π *P body Q*
  assumes *TERMINATES*: $\forall s.\ \exists t.\ \pi$: (*epilogue*,*s*) ⇒ *t*
  shows *HT* π *P* (*body*;;*epilogue*) (λs_0. *sp* π (*Q* s_0) *epilogue*)
  using *assms*
  unfolding *HT-def*
  apply (*simp add*: *wp-eq*)
  apply (*force simp*: *sp-def wp-def*)
  done

Intuition: Scope can be seen as assignment of locals before and after inner command. Thus, this rule is a combined forward and backward assignment rule, for the epilogue *locals*:=<> and the prologue *locals*:=*old-locals*.

lemma *adjust-scope*:

assumes *HT* π *P body Q*
shows *HT* π (λs. *P* <<>|*s*>) (*SCOPE body*) (λs_0 *s*. $\exists$ *l*. *Q* (<<>|s_0>) (<*l*|*s*>))
using *assms* **unfolding** *HT-def*
apply (*auto simp*: *wp-eq combine-nest*)
apply (*auto simp*: *wp-def*)
by (*metis combine-collapse*)

2.12.3 Proof for Recursive Specifications

Prove correct any set of Hoare-triples, e.g., mutually recursive ones.

lemma *HTsetI*:
assumes *wf R*
assumes *RL*: $\bigwedge P\ c\ Q\ s_0$. $[\![$ *HTset-r* ($\lambda c'\ s'$. ((c',s'),(c,s_0))$\in R$) π Θ; (P,c,Q)$\in\Theta$; $P\ s_0$ $]\!]$ $\Longrightarrow$ *wp* π *c* ($Q\ s_0$) s_0
shows *HTset* π Θ
unfolding *HTset-def HT-def*
proof *clarsimp*
fix $P\ c\ Q\ s_0$
assume (P,c,Q)$\in\Theta$ $P\ s_0$
with ‹*wf R*› **show** *wp* π *c* ($Q\ s_0$) s_0

4 Quickstart Guide

theory *Quickstart-Guide*
imports *../IMP2*
begin

4.1 Introductory Examples

IMP2 provides commands to define program snippets or procedures together with their specification.

procedure-spec *div-ab* (*a*,*b*) **returns** *c*
assumes ‹$b\neq 0$›
ensures ‹$c=a_0\ div\ b_0$›
defines ‹$c = a/b$›
by *vcg-cs*

The specification consists of the signature (name, parameters, return variables), precondition, postcondition, and program text.

Signature The procedure name and variable names must be valid Isabelle names. The *returns* declaration is optional, by default, nothing is returned. Multiple values can be returned by *returns* $(x_1,...,x_n)$.

Precondition An Isabelle formula. Parameter names are valid variables.

Postcondition An Isabelle formula over the return variables, and parameter names suffixed with $_0$.

Program Text The procedure body, in a C-like syntax.

The **procedure-spec** command will open a proof to show that the program satisfies the specification. The default way of discharging this goal is by using IMP2's verification condition generator, followed by manual discharging of the generated VCs as necessary.

Note that the *vcg-cs* method will apply *clarsimp* to all generated VCs, which, in our case, already solves them. You can use *vcg* to get the raw VCs.

If the VCs have been discharged, **procedure-spec** adds prologue and epilogue code for parameter passing, defines a constant for the procedure, and lifts the pre- and postcondition over the constant definition.

thm *div-ab-spec* — Final theorem proved
thm *div-ab-def* — Constant definition, with parameter passing code

The final theorem has the form *HT-mods* π *vs* P c Q, where π is an arbitrary procedure environment, *vs* is a syntactic approximation of the (global) variables modified by the procedure, P,Q are the pre- and postcondition, lifted over the parameter passing code, and c is the defined constant for the procedure.

The precondition is a function *state* $\Rightarrow$ *bool*. It starts with a series of variable bindings that map program variables to logical variables, followed by precondition that was specified, wrapped in a *BB-PROTECT* constant, which serves as a tag for the VCG, and is defined as the identity (*BB-PROTECT* $\equiv \lambda a.\ a$).

The final theorem is declared to the VCG, such that the specification will be used automatically for calls to this procedure.

procedure-spec *use-div-ab*(a) **returns** r **assumes** ‹$a{\neq}0$› **ensures** ‹$r{=}1$› **defines** ‹r = *div-ab*(a,a)› **by** *vcg-cs*

4.1.1 Variant and Invariant Annotations

Loops must be annotated with variants and invariants.

procedure-spec *mult-ab*(a,b) **returns** c **assumes** ‹*True*› **ensures** $c{=}a_0{*}b_0$
defines ‹
  if $(a{<}0)$ $\{a = -a;\ b = -b\}$;
  $c{=}0$;
  while $(a{>}0)$
    @*variant* ‹a›
    @*invariant* ‹$0{\le}a \wedge a{\le}|a_0| \wedge c = (\ |a_0| - a) * b_0 * sgn\ a_0$›
  {
    $c{=}c{+}b$;
    $a{=}a{-}1$
  }
›
  apply *vcg-cs*
   apply (*auto simp*: *algebra-simps*)
  done

The variant and invariant can use the program variables. Variables suffixed with $_0$ refer to the values of parameters at the start of the program.

The variant must be an expression of type *int*, which decreases with every loop iteration and is always ≥ 0.

Pitfall: If the variant has a more general type, e.g., $'a$, an explicit type annotation must be added. Otherwise, you'll get an ugly error message directly from Isabelle's type checker!

4.1.2 Recursive Procedures

IMP2 supports mutually recursive procedures. All procedures of a mutually recursive specification have to be specified and proved simultaneously.

Each procedure has to be annotated with a variant over the parameters. On a recursive call, the variant of the callee for the arguments must be smaller than the variant of the caller (for its initial arguments).

Recursive invocations inside the specification have to be tagged by the *rec* keyword.

recursive-spec
  odd-imp(n) **returns** b **assumes** $n{\ge}0$ **ensures** ‹$b{\neq}0 \longleftrightarrow odd\ n_0$›
variant ‹n›
  defines ‹*if* $(n{=}{=}0)$ $b{=}0$ *else* $b{=}rec\ even\text{-}imp(n{-}1)$›
and

even-imp(n) **returns** b **assumes** $n \geq 0$ **ensures** ‹$b \neq 0 \longleftrightarrow$ *even* n_0› **variant** ‹n›
defines ‹*if* ($n == 0$) $b=1$ *else* $b=$*rec odd-imp*($n-1$)›
by *vcg-cs*

After proving the VCs, constants are defined as usual, and the correctness theorems are lifted and declared to the VCG for future use.

thm *odd-imp-spec even-imp-spec*

4.2 The VCG

The VCG is designed to produce human-readable VCs. It takes care of presenting the VCs with reasonable variable names, and a location information from where a VC originates.

```
procedure-spec mult-ab′(a,b) returns c assumes ‹True› ensures
c=a₀∗b₀
  defines ‹
    if (a<0) {a = −a; b = −b};
    c=0;
    while (a>0)
      @variant ‹a›
      @invariant ‹0≤a ∧ a≤|a₀| ∧ c = ( |a₀| − a) ∗ b₀ ∗ sgn a₀›
    {
      c=c+b;
      a=a−1
    }
  ›
  apply vcg
```

The ¶*xxx* tags in the premises give a hint to the origin of each VC. Moreover, the variable names are derived from the actual variable names in the program.

by (*auto simp*: *algebra-simps*)

4.3 Advanced Features

4.3.1 Custom Termination Relations

Both for loops and recursive procedures, a custom termination relation can be specified, with the *relation* annotation. The variant must be a function into the domain of this relation.

Pitfall: You have to ensure, by type annotations, that the most general type of the relation and variant fit together. Otherwise, ugly low-level errors will be the result.

procedure-spec *mult-ab*″(a,b) **returns** c **assumes** ‹*True*› **ensures** $c=a_0*b_0$

defines ‹
if $(a<0)$ $\{a = -a;\ b = -b\}$;
$c{=}0$;
while $(a>0)$
@*relation* ‹*measure nat*›
@*variant* ‹a›
@*invariant* ‹$0 \le a \wedge a \le |a_0| \wedge c = (\ |a_0| - a) * b_0 * sgn\ a_0$›
{
$c{=}c{+}b$;
$a{=}a{-}1$
}
›
by *vcg-cs* (*auto simp*: *algebra-simps*)

recursive-spec relation ‹*measure nat*›
odd-imp'(n) **returns** b **assumes** $n \ge 0$ **ensures** ‹$b \ne 0 \longleftrightarrow odd\ n_0$› **variant** ‹$n$›
defines ‹*if* $(n{=}{=}0)$ $b{=}0$ *else* $b{=}rec$ *even-imp'*$(n{-}1)$›
and
even-imp'(n) **returns** b **assumes** $n \ge 0$ **ensures** ‹$b \ne 0 \longleftrightarrow even\ n_0$› **variant** ‹$n$›
defines ‹*if* $(n{=}{=}0)$ $b{=}1$ *else* $b{=}rec$ *odd-imp'*$(n{-}1)$›
by *vcg-cs*

4.3.2 Partial Correctness

IMP2 supports partial correctness proofs only for while-loops. Recursive procedures must always be proved totally correct[1]

procedure-spec (*partial*) *nonterminating*() **returns** a **assumes** *True* **ensures** ‹$a{=}0$› **defines**
‹*while* $(a \ne 0)$ @*invariant* ‹*True*›
$a{=}a{-}1$›
by *vcg-cs*

4.3.3 Arrays

IMP2 provides one-dimensional arrays of integers, which are indexed by integers. Arrays do not have to be declared or allocated. By default, every index maps to zero.

In the specifications, arrays are modeled as functions of type *int* $\Rightarrow$ *int*.

lemma *array-sum-aux*: $l_0 \le l \Longrightarrow \{l_0..<l + 1\} = insert\ l\ \{l_0..<l\}$ **for** $l_0\ l$ :: *int* **by** *auto*

[1] Adding partial correctness for recursion is possible, however, compared to total correctness, showing that the prove rule is sound requires some effort that we have not (yet) invested.

procedure-spec *array-sum*(a,l,h) **returns** s **assumes** $l \le h$ **ensures** $\langle s = (\sum i{=}l_0..{<}h_0.\ a_0\ i)\rangle$ **defines**

```
  ‹ s=0;
    while (l<h)
      @variant ‹h−l›
      @invariant ‹l₀≤l ∧ l≤h ∧ s = (∑ i=l₀..<l. a i)›
    { s = s+a[l]; l=l+1 } ›
  apply vcg-cs
  apply (simp add: array-sum-aux)
  done
```

4.4 Proving Techniques

This section contains a small collection of techniques to tackle large proofs.

4.4.1 Auxiliary Lemmas

Prove auxiliary lemmas, and try to keep the actual proof of the specification small. As a rule of thumb: All VCs that cannot be solved by a simple *auto* invocation should go to an auxiliary lemma.

The auxiliary lemma may either re-state the whole VC, or only prove the "essence" of the VC, such that the rest of its proof becomes automatic again. See the *array-sum* program above for an example or the latter case.

Pitfall When extracting auxiliary lemmas, it is too easy to get too general types, which may render the lemmas unprovable. As an example, omitting the explicit type constraints from *array-sum-aux* will yield an unprovable statement.

4.4.2 Inlining

More complex procedure bodies can be modularized by either splitting them into multiple procedures, or using inlining and **program-spec** to explicitly prove a specification for a part of a program. Cf. the insertion sort example for the latter technique.

4.4.3 Functional Refinement

Sometimes, it makes sense to state the algorithm functionally first, and then prove that the implementation behaves like the functional program, and, separately, that the functional program is correct. Cf. the mergesort example.

4.4.4 Data Refinement

Moreover, it sometimes makes sense to abstract the concrete variables to abstract types, over which the algorithm is then specified. For example, an array *a* with a range *l*..<*h* can be understood as a list. Or an array can be used as a bitvector set. Cf. the mergesort and dedup examples.

4.5 Troubleshooting

We list a few common problems and their solutions here

4.5.1 Invalid Variables in Annotations

Undeclared variables in annotations are highlighted, however, no warning or error is produced. Usually, the generated VCs will not be provable. The most common mistake is to forget the $_0$ suffix when referring to parameter values in (in)variants and postconditions.

Note the highlighting of unused variables in the following example

```
  procedure-spec foo(x1,x2) returns y assumes x1>x2+x3 ensures y = x1₀+x2 defines ‹
      y=0;
    while (x1>0)
      @variant ‹y + x3›
      @invariant ‹y>x3›
      {
        x1=x2
      }
  ›
  oops
```

Even worse, if the most general type of an annotation becomes too general, as free variables have type $'a$ by default, you will see an internal type error.
Try replacing the variant or invariant with a free variable in the above example.

4.5.2 Wrong Annotations

For total correctness, you must annotate a loop variant and invariant. For partial correctness, you must annotate an invariant, but **no variant**.

When not following this rule, the VCG will get stuck in an internal state

```
procedure-spec (partial) foo () assumes True ensures True defines ‹
  while (n>0) @variant ‹n› @invariant ‹True›
  { n=n−1 }
›
  apply vcg
  oops
```

4.5.3 Calls to Undefined Procedures

Calling an undefined procedure usually results in a type error, as the procedure name gets interpreted as an Isabelle term, e.g., either it refers to an existing constant, or is interpreted as a free variable

4.6 Missing Features

This is an (incomplete) list of missing features.

4.6.1 Elaborate Warnings and Errors

Currently, the IMP2 tools only produce minimal error and warning messages. Quite often, the user sees the raw error message as produced by Isabelle unfiltered, including all internal details of the tools.

4.6.2 Static Type Checking

We do no static type checking at all. In particular, we do not check, nor does our semantic enforce, that procedures are called with the same number of arguments as they were declared. Programs that violate this convention may even have provable properties, as argument and parameter passing is modeled as macros on top of the semantics, and the semantics has no notion of failure.

4.6.3 Structure Types

Every variable is an integer arrays. Plain integer variables are implemented as macros on top of this, by referring to index *0*.

The most urgent addition to increase usability would be record types. With them, we could model encapsulation and data refinement more explicitly, by collecting all parts of a data structure in a single (record-typed) variable.

An easy way of adding record types would follow a similar route as arrays, modeling values of variables as a recursive tree-structured datatype.

datatype $val = PRIM\ int \mid STRUCT\ fname \Rightarrow val \mid ARRAY\ int \Rightarrow val$

However, for modeling the semantics, we most likely want to introduce an explicit error state, to distinguish type errors (e.g. accessing a record field of an integer value) from nontermination.

4.6.4 Function Calls as Expressions

Currently, function calls are modeled as statements, and thus, cannot be nested into expressions. Doing so would require to simultaneously specify the semantics of commands and expressions, which makes things more complex.

As the language is intended to be simple, we have not done this.

4.6.5 Ghost Variables

Ghost variables are a valuable tool for expressing (data) refinement, and hinting the VCG towards the abstract algorithm structure.

We believe that we can add ghost variables with annotations on top of the VCG, without actually changing the program semantics.

4.6.6 Concurrency

IMP2 is a single threaded language. We have no current plans to add concurrency, as this would greatly complicate both the semantics and the VCG, which is contrary to the goal of a simple language for educational purposes.

4.6.7 Pointers and Memory

Adding pointers and memory allocation to IMP2 is theoretically possible, but, again, this would complicate the semantics and the VCG.

However, as the author has some experience in VCGs using separation logic, he might actually add pointers and memory allocation to IMP2 in the near future.

end

5 Introduction to IMP2-VCG, based on IMP

theory *IMP2-from-IMP*
imports *../IMP2*
begin

This document briefly introduces the extensions of IMP2 over IMP.

5.1 Fancy Syntax

Standard Syntax

```
definition exp-count-up1 ≡
  ''a'' ::= N 1;;
  ''c'' ::= N 0;;
  WHILE Cmpop (<) (V ''c'') (V ''n'') DO (
    ''a'' ::= Binop (∗) (N 2) (V ''a'');;
    ''c'' ::= Binop (+) (V ''c'') (N 1))
```

Fancy Syntax

```
definition exp-count-up2 ≡ imp‹
  — Initialization
  a = 1;
  c = 0;
  while (c<n) { — Iterate until c has reached n
    a=2∗a; — Double a
    c=c+1  — Increment c
  }
›

lemma exp-count-up1 = exp-count-up2
  unfolding exp-count-up1-def exp-count-up2-def ..
```

5.2 Operators and Arrays

We reflect arbitrary Isabelle functions into the syntax:

```
value bval (Cmpop (≤) (Binop (+) (Unop uminus (V ''x'')) (N 42))
(N 50)) <''x'':=(λ-. −5)>

thm aval.simps bval.simps
```

Every variable is an array, indexed by integers, no bounds. Syntax shortcuts to access index 0.

term ‹*Vidx ''a'' (i::aexp)*› — Array access at index *i*
lemma *V ''x'' = Vidx ''x'' (N 0)* **..** — Shortcut for access at index *0*

New commands:

term ‹*AssignIdx ''a'' (i::aexp) (v::aexp)*› — Assign at index. Replaces assign.
term ‹*''a''[i] ::= v*› — Standard syntax
term ‹**imp**‹ *a[i] = v* ›› — Fancy syntax

lemma ‹*Assign ''x'' v = AssignIdx ''x'' (N 0) v*› **..** — Shortcut for assignment to index *0*
term ‹*''x'' ::= v*› **term** ‹**imp**‹*x = v+1*››

Note: In fancy syntax, assignment between variables is always parsed as array copy. This is no problem unless a variable is used as both, array and plain value, which should be avoided anyway.

term ‹*ArrayCpy ''d'' ''s''*› — Copy whole array. Both operands are variable names.
term ‹*''d''[] ::= ''s''*› **term** ‹**imp**‹*d = s*››

term ‹*ArrayClear ''a''*› — Initialize array to all zeroes.
term ‹*CLEAR ''a''[]*› **term** ‹**imp**‹*clear a[]*››

Semantics of these is straightforward

thm *big-step.AssignIdx big-step.ArrayCpy big-step.ArrayClear*

5.3 Local and Global Variables

term ‹*is-global*› **term** ‹*is-local*› — Partitions variable names
term ‹$<s_1|s_2>$› — State with locals from s_1 and globals from s_2

term ‹*SCOPE c*› **term** ‹**imp**‹*scope* { *skip* }›› — Execute *c* with fresh set of local variables
thm *big-step.Scope*

5.3.1 Parameter Passing

Parameters and return values by global variables: This is syntactic sugar only:

context fixes *f* :: *com* **begin**

      a = c;
      i = i + 1
    }
  ›
  by vcg-cs (auto simp: algebra-simps)
```

6.1.2 Count down

Essentially the same as count up, but we (ab)use the input variable as a counter.

The invariant is the same as for count-up. Only that we have to compute the actual number of loop iterations by $n_0 - n$. We locally introduce the name c for that.

```
program-spec exp-count-down
  assumes 0≤n
  ensures a = 2^nat n₀
  defines ‹
    a = 1;
    while (n>0)
      @variant ‹n›
      @invariant ‹let c = n₀−n in 0≤n ∧ n≤n₀ ∧ a=2^nat c›
    {
      a=2∗a;
      n=n−1
    }
```

›
apply *vcg-cs*
by (*auto simp*: *algebra-simps nat-distribs*)

6.1.3 Approximate from Below

Used to invert a monotonic function. We count up, until we overshoot the desired result, then we subtract one.

The invariant states that the $r-1$ is not too big. When the loop terminates, $r-1$ is not too big, but r is already too big, so $r-1$ is the desired value (rounding down).

The variant measures the gap that we have to the correct result. Note that the loop will do a final iteration, when the result has been reached exactly. We account for that by adding one, such that the measure also decreases in this case.

program-spec *sqr-approx-below*
  assumes $0 \le n$
  ensures $0 \le r \wedge r^2 \le n_0 \wedge n_0 < (r+1)^2$
  defines ‹
    $r=1$;
    while $(r*r \le n)$
      @*variant* ‹$n + 1 - r*r$›
      @*invariant* ‹$0 \le r \wedge (r-1)^2 \le n_0$›
      { $r = r + 1$ };
    $r = r - 1$
  ›
  apply *vcg*
  by (*auto simp*: *algebra-simps power2-eq-square*)

6.1.4 Bisection

A more efficient way of inverting monotonic functions is by bisection, that is, one keeps track of a possible interval for the solution, and halfs the interval in each step. The program will need $O(\log n)$ iterations, and is thus very efficient in practice.

Although the final algorithm looks quite simple, getting it right can be quite tricky.

The invariant is surprisingly easy, just stating that the solution is in the interval $l..<h$.

lemma $\bigwedge h\ l\ n_0 :: int.$
    $[\![$¶''*invar−final*''; $0 \le n_0$; $\neg\ 1 + l < h$; $0 \le l$; $l < h$; $l * l \le n_0$;
     $n_0 < h * h]\!]$
    $\Longrightarrow n_0 < 1 + (l * l + l * 2)$
  by (*smt mult.commute semiring-normalization-rules*(*3*))

program-spec *sqr-bisect*
assumes $0 \le n$ **ensures** $r^2 \le n_0 \wedge n_0 < (r+1)^2$
defines ‹
$l=0$; $h=n+1$;
while $(l+1 < h)$
@*variant* ‹$h-l$›
@*invariant* ‹$0 \le l \wedge l < h \wedge l^2 \le n \wedge n < h^2$›
{
$m = (l + h) / 2$;
if $(m*m \le n)$ $l=m$ *else* $h=m$
};
$r=l$
›
apply *vcg*

We use quick-and-dirty apply style proof to discharge the VCs

    i=i+1
  }
›
apply vcg-cs
  apply (auto simp: intvs-incdec is-equil-def)
 apply (metis atLeastLessThan-iff eq-iff finite-atLeastLessThan-int sum-diff1)
 apply force
by force
```

6.4.5 Rotate Right

```
program-spec rotate-right
  assumes 0<n
  ensures ∀i∈{0..<n}. a i = a_0 ((i−1) mod n)
  defines ‹
    i = 0;
    prev = a[n − 1];
    while (i < n)
      @invariant ‹
        0 ≤ i ∧ i ≤ n
        ∧ (∀j∈{0..<i}. a j = a_0 ((j−1) mod n))
        ∧ (∀j∈{i..<n}. a j = a_0 j)
        ∧ prev = a_0 ((i−1) mod n)
      ›
      @variant ‹n − i›
    {
      temp = a[i];
      a[i] = prev;
      prev = temp;
      i = i + 1
    }
  ›
  apply vcg-cs
  by (simp add: zmod-minus1)
```

6.4.6 Binary Search, Leftmost Element

We first specify the pre- and postcondition

definition *bin-search-pre a l h* $\longleftrightarrow$ $l \le h \wedge$ *ran-sorted a l h*

definition *bin-search-post a l h x i* $\longleftrightarrow$
$l \le i \wedge i \le h \wedge (\forall i \in \{l..<i\}.\ a\ i < x) \wedge (\forall i \in \{i..<h\}.\ x \le a\ i)$

Then we prove that the program is correct

```
program-spec binsearch
  assumes ‹bin-search-pre a l h›
  ensures ‹bin-search-post a₀ l₀ h₀ x₀ l›
  defines ‹
    while (l < h)
      @variant ‹h−l›
        @invariant ‹l₀≤l ∧ l≤h ∧ h≤h₀ ∧ (∀ i∈{l₀..<l}. a i < x) ∧
(∀ i∈{h..<h₀}. x ≤ a i)›
    {
        m = (l + h) / 2;
        if (a[m] < x) l = m + 1
        else h = m
    }
  ›
  apply vcg-cs
     apply (auto simp: algebra-simps bin-search-pre-def bin-search-post-def)
```

Driving sledgehammer to its limits ...

```
  apply (smt div-add-self1 even-succ-div-two odd-two-times-div-two-succ
ran-sorted-alt)
   by (smt div-add-self1 even-succ-div-two odd-two-times-div-two-succ
ran-sorted-alt)
```

Next, we show that our postcondition (which was easy to prove) implies the expected properties of the algorithm.

```
lemma
  assumes bin-search-pre a l h bin-search-post a l h x i
  shows bin-search-decide-membership: x∈a‘{l..<h} ⟷ (i<h ∧ x =
a i)
    and bin-search-leftmost: x∉a‘{l..<i}

6.4.8 Insertion Sort

We first prove the inner loop. The specification here specifies what the algorithm does as closely as possible, such that it becomes easier to prove. In this case, sortedness is not a precondition for the inner loop to move the key element backwards over all greater elements.

```
definition insort-insert-post l j a₀ a i
  ⟷ (let key = a₀ j in
      i∈{l−1..<j}             — i is in range
    — Content of new array
```

```
    ∧ (∀k∈{l..i}. a k = a₀ k)
    ∧ a (i+1) = key
    ∧ (∀k∈{i+2..j}. a k = a₀ (k−1))
    ∧ a = a₀ on −{l..j}
    — Placement of key
    ∧ (i≥l ⟶ a i ≤ key)  — Element at i smaller than key, if it exists
    ∧ (∀k∈{i+2..j}. a k > key) — Elements ≥i+2 greater than key
    )

  for l j i :: int and a₀ a :: int ⇒ int

program-spec insort-insert
  assumes l<j
  ensures insort-insert-post l j a₀ a i
  defines ‹
    key = a[j];
    i = j−1;
    while (i≥l ∧ a[i]>key)
      @variant ‹i−l+1›
      @invariant ‹l−1≤i ∧ i<j
        ∧ (∀k∈{l..i}. a k = a₀ k)
        ∧ (∀k∈{i+2..j}. a k > key ∧ a k = a₀ (k−1))
        ∧ a = a₀ on −{l..j}
        ›
    {
      a[i+1] = a[i];
      i=i−1
    };
    a[i+1] = key
  ›
  unfolding insort-insert-post-def Let-def
  apply vcg
    apply auto
  by (smt atLeastAtMost-iff)
```

Next, we show that our specification that was easy to prove implies the specification that the outer loop expects:

Invoking *insort-insert* will sort in the element

```
lemma insort-insert-sorted:
  assumes l<j
  assumes insort-insert-post l j a a' i'

6.5 Data Refinement

6.5.1 Filtering

program-spec *array-filter-negative*
  assumes $l \le h$
  ensures *lran a* l_0 *i* = *filter* ($\lambda x.\ x \ge 0$) (*lran* a_0 l_0 h_0)
  defines ‹
    i=*l*; *j*=*l*;
    while ($j<h$)
      @*invariant* ‹
          $l \le i$ ∧ $i \le j$ ∧ $j \le h$
        ∧ *lran a l i* = *filter* ($\lambda x.\ x \ge 0$) (*lran* a_0 *l j*)
        ∧ *lran a j h* = *lran* a_0 *j h*

```
    ›
    @variant ‹h−j›
  {
    if (a[j]≥0) {a[i] = a[j]; i=i+1};
    j=j+1
  }
›
supply lran-eq-iff[simp] lran-tail[simp del]
apply vcg-cs
done
```

6.5.2 Merge Two Sorted Lists

We define the merge function abstractly first, as a functional program on lists.

```
fun merge where
  merge [] ys = ys
| merge xs [] = xs
| merge (x#xs) (y#ys) = (if x<y then x#merge xs (y#ys) else y#merge
(x#xs) ys)

lemma merge-add-simp[simp]: merge xs [] = xs by (cases xs) auto
```

It's straightforward to show that this produces a sorted list with the same elements.

```
lemma merge-sorted:
  assumes sorted xs sorted ys
  shows sorted (merge xs ys) ∧ set (merge xs ys) = set xs ∪ set ys
  using assms
  apply (induction xs ys rule: merge.induct)
    apply auto
  done

lemma merge-mset: mset (merge xs ys) = mset xs + mset ys
  by (induction xs ys rule: merge.induct) auto
```

Next, we prove an equation that characterizes one step of the while loop, on the list level.

```
lemma merge-eq: xs≠[] ∨ ys≠[] ⟹ merge xs ys = (
  if ys=[] ∨ (xs≠[] ∧ hd xs < hd ys) then hd xs # merge (tl xs) ys
  else hd ys # merge xs (tl ys)
  )
  by (cases xs; cases ys; simp)
```

We do a first proof that our merge implementation on the arrays and indexes behaves like the functional merge on the corresponding lists.

The annotations use the *lran* function to map from the implementation level to the list level. Moreover, the invariant of the implementation, $l \le h$, is carried through explicitly.

```
program-spec merge-imp'
  assumes l1≤h1 ∧ l2≤h2
  ensures let ms = lran m 0 j; xs₀ = lran a1₀ l1₀ h1₀; ys₀ = lran
a2₀ l2₀ h2₀ in
    j≥0 ∧ ms = merge xs₀ ys₀
  defines ‹
    j=0;
    while (l1≠h1 ∨ l2≠h2)
      @variant ‹h1 + h2 − l1 − l2›
      @invariant ‹let
          xs=lran a1 l1 h1; ys = lran a2 l2 h2; ms = lran m 0 j;
          xs₀ = lran a1₀ l1₀ h1₀; ys₀ = lran a2₀ l2₀ h2₀
        in
          l1≤h1 ∧ l2≤h2 ∧ 0≤j ∧
          merge xs₀ ys₀ = ms@merge xs ys
      ›
    {
      if (l2==h2 ∨ (l1≠h1 ∧ a1[l1] < a2[l2])) {
        m[j] = a1[l1];
        l1=l1+1
      } else {
        m[j] = a2[l2];
        l2=l2+1
      };
      j=j+1
    }
  ›
```

Given the *merge-eq* theorem, which captures the essence of a loop step, and the theorems $?l \le ?h \Longrightarrow lran\ ?a\ ?l\ (?h + 1) = lran\ ?a\ ?l\ ?h\ @\ [?a\ ?h]$, $lran\ ?a\ (?l + 1)\ ?h = tl\ (lran\ ?a\ ?l\ ?h)$, and $?l < ?h \Longrightarrow hd\ (lran\ ?a\ ?l\ ?h) = ?a\ ?l$, which convert from the operations on arrays and indexes to operations on lists, the proof is straightforward

```
  apply vcg-cs
  subgoal apply (subst merge-eq) by auto
  subgoal by linarith
  subgoal apply (subst merge-eq) by auto
  done
```

In a next step, we refine our proof to combine it with the abstract properties we have proved about merge. The program does not change (we simply inline the original one here).
