

Slicing Guarantees Information Flow Noninterference

Daniel Wasserrab

March 17, 2025

Abstract

In this contribution, we show how correctness proofs for intra- [8] and interprocedural slicing [9] can be used to prove that slicing is able to guarantee information flow noninterference. Moreover, we also illustrate how to lift the control flow graphs of the respective frameworks such that they fulfil the additional assumptions needed in the noninterference proofs. A detailed description of the intraprocedural proof and its interplay with the slicing framework can be found in [10].

1 Introduction

Information Flow Control (IFC) encompasses algorithms which determines if a given program leaks secret information to public entities. The major group are so called IFC type systems, where well-typed means that the respective program is secure. Several IFC type systems have been verified in proof assistants, e.g. see [1, 2, 5, 3, 7].

However, type systems have some drawbacks which can lead to false alarms. To overcome this problem, an IFC approach basing on slicing has been developed [4], which can significantly reduce the amount of false alarms. This contribution presents the first machine-checked proof that slicing is able to guarantee IFC noninterference. It bases on previously published machine-checked correctness proofs for slicing [8, 9]. Details for the intraprocedural case can be found in [10].

2 Slicing guarantees IFC Noninterference

```
theory NonInterferenceIntra imports
  Slicing.Slice
  Slicing.CFGExit-wf
begin
```

2.1 Assumptions of this Approach

Classical IFC noninterference, a special case of a noninterference definition using partial equivalence relations (per) [6], partitions the variables (i.e. locations) into security levels. Usually, only levels for secret or high, written H , and public or low, written L , variables are used. Basically, a program that is noninterferent has to fulfil one basic property: executing the program in two different initial states that may differ in the values of their H -variables yields two final states that again only differ in the values of their H -variables; thus the values of the H -variables did not influence those of the L -variables.

Every per-based approach makes certain assumptions: (i) all H -variables are defined at the beginning of the program, (ii) all L -variables are observed (or used in our terms) at the end and (iii) every variable is either H or L . This security label is fixed for a variable and can not be altered during a program run. Thus, we have to extend the prerequisites of the slicing framework in [8] accordingly in a new locale:

```
locale NonInterferenceIntraGraph =
  BackwardSlice sourcenode targetnode kind valid-edge Entry Def Use state-val
  backward-slice +
  CFGExit-wf sourcenode targetnode kind valid-edge Entry Def Use state-val Exit
for sourcenode :: 'edge => 'node and targetnode :: 'edge => 'node
and kind :: 'edge => 'state edge-kind and valid-edge :: 'edge => bool
and Entry :: 'node (<'(-Entry'-')>) and Def :: 'node => 'var set
and Use :: 'node => 'var set and state-val :: 'state => 'var => 'val
and backward-slice :: 'node set => 'node set
and Exit :: 'node (<'(-Exit'-')>) +
fixes H :: 'var set
fixes L :: 'var set
fixes High :: 'node (<'(-High'-')>)
fixes Low :: 'node (<'(-Low'-')>)
assumes Entry-edge-Exit-or-High:
  [[valid-edge a; sourcenode a = (-Entry-)]]
    ==> targetnode a = (-Exit-)  $\vee$  targetnode a = (-High-)
and High-target-Entry-edge:
   $\exists$  a. valid-edge a  $\wedge$  sourcenode a = (-Entry-)  $\wedge$  targetnode a = (-High-)  $\wedge$ 
    kind a = ( $\lambda s. \text{True}$ ) $_{\vee}$ 
and Entry-predecessor-of-High:
  [[valid-edge a; targetnode a = (-High-)] ==> sourcenode a = (-Entry-)]
and Exit-edge-Entry-or-Low: [[valid-edge a; targetnode a = (-Exit-)]]
    ==> sourcenode a = (-Entry-)  $\vee$  sourcenode a = (-Low-)
and Low-source-Exit-edge:
   $\exists$  a. valid-edge a  $\wedge$  sourcenode a = (-Low-)  $\wedge$  targetnode a = (-Exit-)  $\wedge$ 
    kind a = ( $\lambda s. \text{True}$ ) $_{\vee}$ 
and Exit-successor-of-Low:
  [[valid-edge a; sourcenode a = (-Low-)] ==> targetnode a = (-Exit-)]
and DefHigh: Def (-High-) = H
and UseHigh: Use (-High-) = H
```

```

and UseLow: Use (-Low-) = L
and HighLowDistinct: H ∩ L = {}
and HighLowUNIV: H ∪ L = UNIV

begin

lemma Low-neq-Exit: assumes L ≠ {} shows (-Low-) ≠ (-Exit-)
⟨proof⟩

lemma Entry-path-High-path:
assumes (-Entry-) –as→* n and inner-node n
obtains a' as' where as = a'#as' and (-High-) –as'→* n
and kind a' = ( $\lambda s. \text{True}$ ) $\vee$ 
⟨proof⟩

lemma Exit-path-Low-path:
assumes n –as→* (-Exit-) and inner-node n
obtains a' as' where as = as'@[a'] and n –as'→* (-Low-)
and kind a' = ( $\lambda s. \text{True}$ ) $\vee$ 
⟨proof⟩

lemma not-Low-High: V ∉ L  $\implies$  V ∈ H
⟨proof⟩

lemma not-High-Low: V ∉ H  $\implies$  V ∈ L
⟨proof⟩

```

2.2 Low Equivalence

In classical noninterference, an external observer can only see public values, in our case the *L*-variables. If two states agree in the values of all *L*-variables, these states are indistinguishable for him. *Low equivalence* groups those states in an equivalence class using the relation \approx_L :

```

definition lowEquivalence :: 'state  $\Rightarrow$  'state  $\Rightarrow$  bool (infixl  $\approx_L$  50)
where s  $\approx_L$  s'  $\equiv$   $\forall V \in L. \text{state-val } s \ V = \text{state-val } s' \ V$ 

```

The following lemmas connect low equivalent states with relevant variables as necessary in the correctness proof for slicing.

```

lemma relevant-vars-Entry:
assumes V ∈ rv S (-Entry-) and (-High-)  $\notin$  backward-slice S
shows V ∈ L
⟨proof⟩

```

lemma *lowEquivalence-relevant-nodes-Entry*:
assumes $s \approx_L s'$ **and** $(-\text{High}-) \notin \text{backward-slice } S$
shows $\forall V \in \text{rv } S \text{ } (-\text{Entry}-). \text{state-val } s \text{ } V = \text{state-val } s' \text{ } V$
(proof)

lemma *rv-Low-Use-Low*:
assumes $(-\text{Low}-) \in S$
shows $\llbracket n - \text{as} \rightarrow^* (-\text{Low}-); n - \text{as}' \rightarrow^* (-\text{Low}-);$
 $\forall V \in \text{rv } S \text{ } n. \text{state-val } s \text{ } V = \text{state-val } s' \text{ } V;$
 $\text{preds}(\text{slice-kinds } S \text{ } as) \text{ } s; \text{preds}(\text{slice-kinds } S \text{ } as') \text{ } s' \rrbracket$
 $\implies \forall V \in \text{Use } (-\text{Low}-). \text{state-val } (\text{transfers}(\text{slice-kinds } S \text{ } as) \text{ } s) \text{ } V =$
 $\text{state-val } (\text{transfers}(\text{slice-kinds } S \text{ } as') \text{ } s') \text{ } V$
(proof)

2.3 The Correctness Proofs

In the following, we present two correctness proofs that slicing guarantees IFC noninterference. In both theorems, $(-\text{High}-) \notin \text{backward-slice } S$, where $(-\text{Low}-) \in S$, makes sure that no high variable (which are all defined in $(-\text{High}-)$) can influence a low variable (which are all used in $(-\text{Low}-)$).

First, a theorem regarding $(-\text{Entry}-) - \text{as} \rightarrow^* (-\text{Exit}-)$ paths in the control flow graph (CFG), which agree to a complete program execution:

lemma *nonInterference-path-to-Low*:
assumes $s \approx_L s'$ **and** $(-\text{High}-) \notin \text{backward-slice } S$ **and** $(-\text{Low}-) \in S$
and $(-\text{Entry}-) - \text{as} \rightarrow^* (-\text{Low}-)$ **and** $\text{preds}(\text{kinds } as) \text{ } s$
and $(-\text{Entry}-) - \text{as}' \rightarrow^* (-\text{Low}-)$ **and** $\text{preds}(\text{kinds } as') \text{ } s'$
shows $\text{transfers}(\text{kinds } as) \text{ } s \approx_L \text{transfers}(\text{kinds } as') \text{ } s'$
(proof)

theorem *nonInterference-path*:
assumes $s \approx_L s'$ **and** $(-\text{High}-) \notin \text{backward-slice } S$ **and** $(-\text{Low}-) \in S$
and $(-\text{Entry}-) - \text{as} \rightarrow^* (-\text{Exit}-)$ **and** $\text{preds}(\text{kinds } as) \text{ } s$
and $(-\text{Entry}-) - \text{as}' \rightarrow^* (-\text{Exit}-)$ **and** $\text{preds}(\text{kinds } as') \text{ } s'$
shows $\text{transfers}(\text{kinds } as) \text{ } s \approx_L \text{transfers}(\text{kinds } as') \text{ } s'$
(proof)

end

The second theorem assumes that we have a operational semantics, whose evaluations are written $\langle c, s \rangle \Rightarrow \langle c', s' \rangle$ and which conforms to the CFG. The correctness theorem then states that if no high variable influenced a low variable and the initial states were low equivalent, the resulting states are again low equivalent:

locale *NonInterferenceIntra* =

```

NonInterferenceIntraGraph sourcenode targetnode kind valid-edge Entry
  Def Use state-val backward-slice Exit H L High Low +
  BackwardsSlice-wf sourcenode targetnode kind valid-edge Entry Def Use state-val
    backward-slice sem identifies
  for sourcenode :: 'edge => 'node and targetnode :: 'edge => 'node
  and kind :: 'edge => 'state edge-kind and valid-edge :: 'edge => bool
  and Entry :: 'node (<'(-Entry'-')>) and Def :: 'node => 'var set
  and Use :: 'node => 'var set and state-val :: 'state => 'var => 'val
  and backward-slice :: 'node set => 'node set
  and sem :: 'com => 'state => 'com => 'state => bool
  (((1<-,/->) =>/ (1<-,/->)) [0,0,0,0] 81)
  and identifies :: 'node => 'com => bool (<-  $\triangleq$  -> [51, 0] 80)
  and Exit :: 'node (<'(-Exit'-')>)
  and H :: 'var set and L :: 'var set
  and High :: 'node (<'(-High'-')>) and Low :: 'node (<'(-Low'-')>) +
  fixes final :: 'com => bool
  assumes final-edge-Low: [[final c; n  $\triangleq$  c]]
   $\implies \exists a.$  valid-edge a  $\wedge$  sourcenode a = n  $\wedge$  targetnode a = (-Low-)  $\wedge$  kind a =
 $\uparrow id$ 
begin

```

The following theorem needs the explicit edge from (-High-) to n. An approach using a *init* predicate for initial statements, being reachable from (-High-) via a $(\lambda s. \text{True})_{\vee}$ edge, does not work as the same statement could be identified by several nodes, some initial, some not. E.g., in the program `while (True) Skip;;Skip` two nodes identify this initial statement: the initial node and the node within the loop (because of loop unrolling).

```

theorem nonInterference:
  assumes  $s_1 \approx_L s_2$  and (-High-)  $\notin$  backward-slice S and (-Low-)  $\in S$ 
  and valid-edge a and sourcenode a = (-High-) and targetnode a = n
  and kind a =  $(\lambda s. \text{True})_{\vee}$  and  $n \triangleq c$  and final c'
  and  $\langle c, s_1 \rangle \Rightarrow \langle c', s_1 \rangle$  and  $\langle c, s_2 \rangle \Rightarrow \langle c', s_2 \rangle$ 
  shows  $s_1' \approx_L s_2'$ 
  ⟨proof⟩

```

end

end

3 Framework Graph Lifting for Noninterference

```

theory LiftingIntra
  imports NonInterferenceIntra Slicing.CDepInstantiations
begin

```

In this section, we show how a valid CFG from the slicing framework in [8] can be lifted to fulfil all properties of the *NonInterferenceIntraGraph*

locale. Basically, we redefine the hitherto existing *Entry* and *Exit* nodes as new *High* and *Low* nodes, and introduce two new nodes *NewEntry* and *NewExit*. Then, we have to lift all functions to operate on this new graph.

3.1 Liftings

3.1.1 The datatypes

```
datatype 'node LDCFG-node = Node 'node
| NewEntry
| NewExit

type-synonym ('edge,'node,'state) LDCFG-edge =
'node LDCFG-node × ('state edge-kind) × 'node LDCFG-node
```

3.1.2 Lifting *valid-edge*

```
inductive lift-valid-edge :: ('edge ⇒ bool) ⇒ ('edge ⇒ 'node) ⇒ ('edge ⇒ 'node)
⇒
('edge ⇒ 'state edge-kind) ⇒ 'node ⇒ 'node ⇒ ('edge,'node,'state) LDCFG-edge
⇒
bool
for valid-edge::'edge ⇒ bool and src::'edge ⇒ 'node and trg::'edge ⇒ 'node
and knd::'edge ⇒ 'state edge-kind and E::'node and X::'node

where lve-edge:
[valid-edge a; src a ≠ E ∨ trg a ≠ X;
e = (Node (src a),knd a,Node (trg a))]
⇒ lift-valid-edge valid-edge src trg knd E X e

| lve-Entry-edge:
e = (NewEntry,(λs. True)∨,Node E)
⇒ lift-valid-edge valid-edge src trg knd E X e

| lve-Exit-edge:
e = (Node X,(λs. True)∨,NewExit)
⇒ lift-valid-edge valid-edge src trg knd E X e

| lve-Entry-Exit-edge:
e = (NewEntry,(λs. False)∨,NewExit)
⇒ lift-valid-edge valid-edge src trg knd E X e
```

```
lemma [simp]:¬ lift-valid-edge valid-edge src trg knd E X (Node E,et,Node X)
⟨proof⟩
```

3.1.3 Lifting *Def* and *Use* sets

```
inductive-set lift-Def-set :: ('node ⇒ 'var set) ⇒ 'node ⇒ 'node ⇒
```

```

 $'var \text{ set} \Rightarrow 'var \text{ set} \Rightarrow ('node \text{ LDCFG-node} \times 'var) \text{ set}$ 
for  $\text{Def}::('node \Rightarrow 'var \text{ set}) \text{ and } E::'node \text{ and } X::'node$ 
and  $H::'var \text{ set} \text{ and } L::'var \text{ set}$ 

where lift-Def-node:
 $V \in \text{Def } n \implies (\text{Node } n, V) \in \text{lift-Def-set Def } E X H L$ 

 $| \text{ lift-Def-High:}$ 
 $V \in H \implies (\text{Node } E, V) \in \text{lift-Def-set Def } E X H L$ 

abbreviation  $\text{lift-Def} :: ('node \Rightarrow 'var \text{ set}) \Rightarrow 'node \Rightarrow 'node \Rightarrow$ 
 $'var \text{ set} \Rightarrow 'var \text{ set} \Rightarrow ('node \text{ LDCFG-node} \Rightarrow 'var \text{ set}) \text{ set}$ 
where  $\text{lift-Def Def } E X H L n \equiv \{V. (n, V) \in \text{lift-Def-set Def } E X H L\}$ 

inductive-set  $\text{lift-Use-set} :: ('node \Rightarrow 'var \text{ set}) \Rightarrow 'node \Rightarrow 'node \Rightarrow$ 
 $'var \text{ set} \Rightarrow 'var \text{ set} \Rightarrow ('node \text{ LDCFG-node} \times 'var) \text{ set}$ 
for  $\text{Use}::'node \Rightarrow 'var \text{ set} \text{ and } E::'node \text{ and } X::'node$ 
and  $H::'var \text{ set} \text{ and } L::'var \text{ set}$ 

where
lift-Use-node:
 $V \in \text{Use } n \implies (\text{Node } n, V) \in \text{lift-Use-set Use } E X H L$ 

 $| \text{ lift-Use-High:}$ 
 $V \in H \implies (\text{Node } E, V) \in \text{lift-Use-set Use } E X H L$ 

 $| \text{ lift-Use-Low:}$ 
 $V \in L \implies (\text{Node } X, V) \in \text{lift-Use-set Use } E X H L$ 

abbreviation  $\text{lift-Use} :: ('node \Rightarrow 'var \text{ set}) \Rightarrow 'node \Rightarrow 'node \Rightarrow$ 
 $'var \text{ set} \Rightarrow 'var \text{ set} \Rightarrow ('node \text{ LDCFG-node} \Rightarrow 'var \text{ set}) \text{ set}$ 
where  $\text{lift-Use Use } E X H L n \equiv \{V. (n, V) \in \text{lift-Use-set Use } E X H L\}$ 

```

3.2 The lifting lemmas

3.2.1 Lifting the basic locales

abbreviation $\text{src} :: ('edge, 'node, 'state) \text{ LDCFG-edge} \Rightarrow 'node \text{ LDCFG-node}$
where $\text{src } a \equiv \text{fst } a$

abbreviation $\text{trg} :: ('edge, 'node, 'state) \text{ LDCFG-edge} \Rightarrow 'node \text{ LDCFG-node}$
where $\text{trg } a \equiv \text{snd } (\text{snd } a)$

definition $\text{knd} :: ('edge, 'node, 'state) \text{ LDCFG-edge} \Rightarrow 'state \text{ edge-kind}$
where $\text{knd } a \equiv \text{fst } (\text{snd } a)$

lemma *lift-CFG*:

```
