## 7.20 Indexing variables in variable lists

**theory** ListIndex **imports** Main **begin**

In order to support local variables and arbitrarily nested blocks, the local variables are arranged as an indexed list. The outermost local variable (“this”) is the first element in the list, the most recently created local variable the last element. When descending into a block structure, a corresponding list  $Vs$  of variable names is maintained. To find the index of some variable  $V$ , we have to find the index of the *last* occurrence of  $V$  in  $Vs$ . This is what *index*

does:

```
primrec index :: 'a list  $\Rightarrow$  'a  $\Rightarrow$  nat
where
  index [] y = 0
| index (x#xs) y =
  (if x=y then if x  $\in$  set xs then index xs y + 1 else 0 else index xs y + 1)
```

```
definition hidden :: 'a list  $\Rightarrow$  nat  $\Rightarrow$  bool
where hidden xs i  $\equiv$  i < size xs  $\wedge$  xs!i  $\in$  set(drop (i+1) xs)
```

### 7.20.1 index

```
lemma [simp]: index (xs @ [x]) x = size xs
```

```
lemma [simp]: (index (xs @ [x]) y = size xs) = (x = y)
```

```
lemma [simp]: x  $\in$  set xs  $\implies$  xs ! index xs x = x
```

```
lemma [simp]: x  $\notin$  set xs  $\implies$  index xs x = size xs
```

```
lemma index-size-conv[simp]: (index xs x = size xs) = (x  $\notin$  set xs)
```

```
lemma size-index-conv[simp]: (size xs = index xs x) = (x  $\notin$  set xs)
```

```
lemma (index xs x < size xs) = (x  $\in$  set xs)
```

```

## 8.4 Axiomatic specification of the JMM

**theory** *JMM-Spec*

**imports**

*Orders*

*../Common/Observable-Events*

*Coinductive.Coinductive-List*

**begin**

### 8.4.1 Definitions

**type-synonym** *JMM-action* = *nat*

**type-synonym** (*'addr, 'thread-id*) *execution* = (*'thread-id* × (*'addr, 'thread-id*) *obs-event action*) *llist*

**definition** *actions* :: (*'addr, 'thread-id*) *execution*  $\Rightarrow$  *JMM-action set*

**where**  $actions\ E = \{n. enat\ n < llength\ E\}$

**definition**  $action-tid :: ('addr, 'thread-id)\ execution \Rightarrow JMM-action \Rightarrow 'thread-id$

**where**  $action-tid\ E\ a = fst\ (lnth\ E\ a)$

**definition**  $action-obs :: ('addr, 'thread-id)\ execution \Rightarrow JMM-action \Rightarrow ('addr, 'thread-id)\ obs-event\ action$

**where**  $action-obs\ E\ a = snd\ (lnth\ E\ a)$

**definition**  $tactions :: ('addr, 'thread-id)\ execution \Rightarrow 'thread-id \Rightarrow JMM-action\ set$

**where**  $tactions\ E\ t = \{a. a \in actions\ E \wedge action-tid\ E\ a = t\}$

**inductive**  $is-new-action :: ('addr, 'thread-id)\ obs-event\ action \Rightarrow bool$

**where**

$NewHeapElem: is-new-action\ (NormalAction\ (NewHeapElem\ a\ hT))$

**inductive**  $is-write-action :: ('addr, 'thread-id)\ obs-event\ action \Rightarrow bool$

**where**

$NewHeapElem: is-write-action\ (NormalAction\ (NewHeapElem\ ad\ hT))$

$| WriteMem: is-write-action\ (NormalAction\ (WriteMem\ ad\ al\ v))$

Initialisation actions are synchronisation actions iff they initialize volatile fields – cf. JMM mailing list, message no. 62 (5 Nov. 2006). However, intuitively correct programs might not be correctly synchronized:

```

x = 0
-----
r1 = x | r2 = x

```

Here, if  $x$  is not volatile, the initial write can belong to at most one thread. Hence, it is happens-before to either  $r1 = x$  or  $r2 = x$ , but not both. In any sequentially consistent execution, both reads must read from the initialisation action  $x = 0$ , but it is not happens-before ordered to one of them.

Moreover, if only volatile initialisations synchronize-with all thread-start actions, this breaks the proof of the DRF guarantee since it assumes that the happens-before relation  $\leq_{hb} a$  for an action  $a$  in a topologically sorted action sequence depends only on the actions before it. Counter example: ( $y$  is volatile)

$[(t1, start), (t1, init\ x), (t2, start), (t1, init\ y), \dots]$

Here,  $(t1, init\ x) \leq_{hb} (t2, start)$  via:  $(t1, init\ x) \leq_{po} (t1, init\ y) \leq_{sw} (t2, start)$ , but in  $[(t1, start), (t1, init\ x), (t2, start)]$ , not  $(t1, init\ x) \leq_{hb} (t2, start)$ .

Sevcik speculated that one might add an initialisation thread which performs all initialisation actions. All normal threads' start action would then synchronize on the final action of the initialisation thread. However, this contradicts the memory chain condition in the final field extension to the JMM (threads must read addresses of objects that they have not created themselves before they can access the fields of the object at that address) – not modelled here.

Instead, we leave every initialisation action in the thread it belongs to, but order it explicitly before the thread's start action and add synchronizes-with edges from *all* initialisation actions to *all* thread start actions.

**inductive**  $saction :: 'm\ prog \Rightarrow ('addr, 'thread-id)\ obs-event\ action \Rightarrow bool$

**for**  $P :: 'm\ prog$

**where**

$NewHeapElem: saction\ P\ (NormalAction\ (NewHeapElem\ a\ hT))$

```

| Read: is-volatile P al  $\implies$  saction P (NormalAction (ReadMem a al v))
| Write: is-volatile P al  $\implies$  saction P (NormalAction (WriteMem a al v))
| ThreadStart: saction P (NormalAction (ThreadStart t))
| ThreadJoin: saction P (NormalAction (ThreadJoin t))
| SyncLock: saction P (NormalAction (SyncLock a))
| SyncUnlock: saction P (NormalAction (SyncUnlock a))
| ObsInterrupt: saction P (NormalAction (ObsInterrupt t))
| ObsInterrupted: saction P (NormalAction (ObsInterrupted t))
| InitialThreadAction: saction P InitialThreadAction
| ThreadFinishAction: saction P ThreadFinishAction

```

**definition** *sactions* :: 'm prog  $\Rightarrow$  ('addr, 'thread-id) execution  $\Rightarrow$  JMM-action set  
**where** *sactions* P E = {a. a  $\in$  actions E  $\wedge$  saction P (action-obs E a)}

**inductive-set** *write-actions* :: ('addr, 'thread-id) execution  $\Rightarrow$  JMM-action set  
**for** E :: ('addr, 'thread-id) execution  
**where**

*write-actions*I:  $\llbracket a \in \text{actions } E; \text{is-write-action (action-obs } E \text{ } a) \rrbracket \implies a \in \text{write-actions } E$

*NewObj* and *NewArr* actions only initialize those fields and array cells that are in fact in the object or array. Hence, they are not a write for - reads from addresses for which no object/array is created during the whole execution - reads from fields/cells that are not part of the object/array at the specified address.

**primrec** *addr-locs* :: 'm prog  $\Rightarrow$  htype  $\Rightarrow$  addr-loc set  
**where**

```

addr-locs P (Class-type C) = {CField D F | D F.  $\exists$  fm T. P  $\vdash$  C has F:T (fm) in D}
| addr-locs P (Array-type T n) = ({ACell n' | n'. n' < n}  $\cup$  {CField Object F | F.  $\exists$  fm T. P  $\vdash$  Object has F:T (fm) in Object})

```

*action-loc-aux* would naturally be an inductive set, but *inductive\_set* does not allow to pattern match on parameters. Hence, specify it using function and derive the setup manually.

**fun** *action-loc-aux* :: 'm prog  $\Rightarrow$  ('addr, 'thread-id) obs-event action  $\Rightarrow$  ('addr  $\times$  addr-loc) set  
**where**

```

action-loc-aux P (NormalAction (NewHeapElem ad (Class-type C))) =
  {(ad, CField D F) | D F T fm. P  $\vdash$  C has F:T (fm) in D}
| action-loc-aux P (NormalAction (NewHeapElem ad (Array-type T n'))) =
  {(ad, ACell n) | n. n < n'}  $\cup$  {(ad, CField D F) | D F T fm. P  $\vdash$  Object has F:T (fm) in D}
| action-loc-aux P (NormalAction (WriteMem ad al v)) = {(ad, al)}
| action-loc-aux P (NormalAction (ReadMem ad al v)) = {(ad, al)}
| action-loc-aux - - = {}

```

**lemma** *action-loc-aux-intros* [intro?]:

```

P  $\vdash$  class-type-of hT has F:T (fm) in D  $\implies$  (ad, CField D F)  $\in$  action-loc-aux P (NormalAction (NewHeapElem ad hT))

external actions must be committed as soon as hb-subsequent actions are committed – JMM constraint 9

**definition** *external-actions-committed* :: bool **where**

*external-actions-committed*  $\longleftrightarrow$   
 $(\forall n. \forall a \in \text{external-actions } (\text{justifying-exec } (J \ n)). \forall a' \in \text{committed } (J \ n).$   
 $P.\text{justifying-exec } (J \ n) \vdash a \leq_{\text{hb}} a' \longrightarrow a \in \text{committed } (J \ n))$

well-formedness conditions for action translations

**definition** *wf-action-translations* :: bool **where**

*wf-action-translations*  $\longleftrightarrow$   
 $(\forall n. \text{wf-action-translation-on } (\text{justifying-exec } (J \ n)) \ E \ (\text{committed } (J \ n)) \ (\text{action-translation } (J \ n)))$

**end**

Rule 8 of the justification for the JMM is incorrect because there might be no transitive reduction of the happens-before relation for an infinite execution, if infinitely many initialisation actions have to be ordered before the start action of every thread. Hence, *is-justified-by* omits this constraint.

**primrec** *is-justified-by* ::

$'m \text{ prog} \Rightarrow ('addr, 'thread-id) \text{ execution} \times \text{write-seen} \Rightarrow ('addr, 'thread-id) \text{ justification} \Rightarrow \text{bool}$   
 $(- \vdash - \text{justified'-by } - [51, 50, 50] \ 50)$

**where**

$P \vdash (E, \text{ws}) \text{ justified-by } J \longleftrightarrow$   
 $\text{is-commit-sequence } E \ J \wedge$   
 $\text{justification-well-formed } P \ J \wedge$   
 $\text{committed-subset-actions } J \wedge$   
 $\text{happens-before-committed } P \ E \ J \wedge$   
 $\text{sync-order-committed } P \ E \ J \wedge$   
 $\text{value-written-committed } P \ E \ J \wedge$   
 $\text{write-seen-committed } \text{ws } J \wedge$   
 $\text{uncommitted-reads-see-hb } P \ J \wedge$   
 $\text{committed-reads-see-committed-writes } \text{ws } J \wedge$   
 $\text{external-actions-committed } P \ J \wedge$   
 $\text{wf-action-translations } E \ J$

Sevcik requires in the fixed JMM that external actions may only be committed when everything that happens before has already been committed. On the level of legality, this constraint is vacuous because it is always possible to delay committing external actions, so we omit it here.

**primrec** *is-weakly-justified-by* ::

$'m \text{ prog} \Rightarrow ('addr, 'thread-id) \text{ execution} \times \text{write-seen} \Rightarrow ('addr, 'thread-id) \text{ justification} \Rightarrow \text{bool}$   
 $(- \vdash - \text{weakly'-justified'-by } - [51, 50, 50] \ 50)$

*uncommitted-reads-see-hb*  $P \ J \wedge$   
*committed-reads-see-committed-writes-weak*  $ws \ J \wedge$   
*wf-action-translations*  $E \ J$

Notion of conflict is strengthened to explicitly exclude volatile locations. Otherwise, the following program is not correctly synchronised:

```

volatile x = 0;
-----
r = x; | x = 1;

```

because in the SC execution [Init x 0, (t1, Read x 0), (t2, Write x 1)], the read and write are unrelated in hb, because synchronises-with is asymmetric for volatiles.

The JLS considers conflicting volatiles for data races, but this is only a remark on the DRF guarantee. See JMM mailing list posts #2477 to 2488.
