7.20 Indexing variables in variable lists

theory *ListIndex* **imports** *Main* **begin**

In order to support local variables and arbitrarily nested blocks, the local variables are arranged as an indexed list. The outermost local variable ("this") is the first element in the list, the most recently created local variable the last element. When descending into a block structure, a corresponding list *Vs* of variable names is maintained. To find the index of some variable *V*, we have to find the index of the *last* occurrence of *V* in *Vs*. This is what *index*

does:

primrec *index* :: *'a list* ⇒ *'a* ⇒ *nat*
where
  index [] *y* = *0*
| *index* (*x*#*xs*) *y* =
  (*if x=y then if x* ∈ *set xs then index xs y* + *1 else 0 else index xs y* + *1*)

definition *hidden* :: *'a list* ⇒ *nat* ⇒ *bool*
where *hidden xs i* ≡ *i* < *size xs* ∧ *xs*!*i* ∈ *set*(*drop* (*i*+*1*) *xs*)

inductive *is-write-action* :: (*'addr*, *'thread-id*) *obs-event action* ⇒ *bool*
where
NewHeapElem: *is-write-action* (*NormalAction* (*NewHeapElem ad hT*))
| *WriteMem*: *is-write-action* (*NormalAction* (*WriteMem ad al v*))

Initialisation actions are synchronisation actions iff they initialize volatile fields – cf. JMM mailing list, message no. 62 (5 Nov. 2006). However, intuitively correct programs might not be correctly synchronized:

```
     x = 0
---------------
r1 = x | r2 = x
```

Here, if x is not volatile, the initial write can belong to at most one thread. Hence, it is happens-before to either r1 = x or r2 = x, but not both. In any sequentially consistent execution, both reads must read from the initilisation action x = 0, but it is not happens-before ordered to one of them.

Moreover, if only volatile initialisations synchronize-with all thread-start actions, this breaks the proof of the DRF guarantee since it assumes that the happens-before relation <= *hb* a for an action *a* in a topologically sorted action sequence depends only on the actions before it. Counter example: (y is volatile)

[(t1, start), (t1, init x), (t2, start), (t1, init y), ...

Here, (t1, init x) <= *hb* (t2, start) via: (t1, init x) <= *po* (t1, init y) <= *sw* (t2, start), but in [(t1, start), (t1, init x), (t2, start)], not (t1, init x) <= *hb* (t2, start).

Sevcik speculated that one might add an initialisation thread which performs all initialisation actions. All normal threads' start action would then synchronize on the final action of the initialisation thread. However, this contradicts the memory chain condition in the final field extension to the JMM (threads must read addresses of objects that they have not created themselves before they can access the fields of the object at that address) – not modelled here.

Instead, we leave every initialisation action in the thread it belongs to, but order it explicitly before the thread's start action and add synchronizes-with edges from *all* initialisation actions to *all* thread start actions.

inductive *saction* :: *'m prog* ⇒ (*'addr*, *'thread-id*) *obs-event action* ⇒ *bool*
for *P* :: *'m prog*
where
NewHeapElem: *saction P* (*NormalAction* (*NewHeapElem a hT*))

| *Read*: *is-volatile P al* $\Longrightarrow$ *saction P* (*NormalAction* (*ReadMem a al v*))
| *Write*: *is-volatile P al* $\Longrightarrow$ *saction P* (*NormalAction* (*WriteMem a al v*))
| *ThreadStart*: *saction P* (*NormalAction* (*ThreadStart t*))
| *ThreadJoin*: *saction P* (*NormalAction* (*ThreadJoin t*))
| *SyncLock*: *saction P* (*NormalAction* (*SyncLock a*))
| *SyncUnlock*: *saction P* (*NormalAction* (*SyncUnlock a*))
| *ObsInterrupt*: *saction P* (*NormalAction* (*ObsInterrupt t*))
| *ObsInterrupted*: *saction P* (*NormalAction* (*ObsInterrupted t*))
| *InitialThreadAction*: *saction P InitialThreadAction*
| *ThreadFinishAction*: *saction P ThreadFinishAction*

definition *sactions* :: *'m prog* $\Rightarrow$ (*'addr*, *'thread-id*) *execution* $\Rightarrow$ *JMM-action set*
where *sactions P E* = {*a*. *a* $\in$ *actions E* $\wedge$ *saction P* (*action-obs E a*)}

inductive-set *write-actions* :: (*'addr*, *'thread-id*) *execution* $\Rightarrow$ *JMM-action set*
for *E* :: (*'addr*, *'thread-id*) *execution*
where
write-actionsI: ⟦ *a* $\in$ *actions E*; *is-write-action* (*action-obs E a*) ⟧ $\Longrightarrow$ *a* $\in$ *write-actions E*

NewObj and *NewArr* actions only initialize those fields and array cells that are in fact in the object or array. Hence, they are not a write for - reads from addresses for which no object/array is created during the whole execution - reads from fields/cells that are not part of the object/array at the specified address.

primrec *addr-locs* :: *'m prog* $\Rightarrow$ *htype* $\Rightarrow$ *addr-loc set*
where
addr-locs P (*Class-type C*) = {*CField D F*|*D F*. $\exists$*fm T*. *P* $\vdash$ *C has F*:*T* (*fm*) *in D*}

in r ∈ *committed-n* ∨ *ws r* ∈ *committed-n*)

external actions must be committed as soon as hb-subsequent actions are committed – JMM constraint 9

definition *external-actions-committed* :: *bool* **where**
external-actions-committed ⟷
(∀ *n*. ∀ *a* ∈ *external-actions* (*justifying-exec* (*J n*)). ∀ *a'* ∈ *committed* (*J n*).
P,*justifying-exec* (*J n*) ⊢ *a* ≤*hb a'* ⟶ *a* ∈ *committed* (*J n*))

well-formedness conditions for action translations

definition *wf-action-translations* :: *bool* **where**
wf-action-translations ⟷
(∀ *n*. *wf-action-translation-on* (*justifying-exec* (*J n*)) *E* (*committed* (*J n*)) (*action-translation* (*J n*)))

end

Rule 8 of the justification for the JMM is incorrect because there might be no transitive reduction of the happens-before relation for an infinite execution, if infinitely many initialisation actions have to be ordered before the start action of every thread. Hence, *is-justified-by* omits this constraint.

primrec *is-justified-by* ::
'm prog ⇒ (*'addr*, *'thread-id*) *execution* × *write-seen* ⇒ (*'addr*, *'thread-id*) *justification* ⇒ *bool*
(‹- ⊢ - *justified'-by* -› [*51*, *50*, *50*] *50*)
where
P ⊢ (*E*, *ws*) *justified-by J* ⟷
is-commit-sequence E J ∧
justification-well-formed P J ∧
committed-subset-actions J ∧
happens-before-committed P E J ∧
sync-order-committed P E J ∧
value-written-committed P E J ∧
write-seen-committed ws J ∧
uncommitted-reads-see-hb P J ∧
committed-reads-see-committed-writes ws J ∧
external-actions-committed P J ∧
wf-action-translations E J

Sevcik requires in the fixed JMM that external actions may only be committed when everything that happens before has already been committed. On the level of legality, this constraint is vacuous because it is always possible to delay committing external actions, so we omit it here.

primrec *is-weakly-justified-by* ::
'm prog ⇒ (*'addr*, *'thread-id*) *execution* × *write-seen* ⇒ (*'addr*, *'thread-id*) *justification* ⇒ *bool*
(‹- ⊢ - *weakly'-justified'-by* -› [*51*, *50*, *50*] *50*)

— no *sync-order* constraint
value-written-committed P E J ∧
write-seen-committed ws J ∧
uncommitted-reads-see-hb P J ∧
committed-reads-see-committed-writes-weak ws J ∧
wf-action-translations E J

Notion of conflict is strengthened to explicitly exclude volatile locations. Otherwise, the following program is not correctly synchronised:

```
volatile x = 0;
---------------
r = x; | x = 1;
```

because in the SC execution [Init x 0, (t1, Read x 0), (t2, Write x 1)], the read and write are unrelated in hb, because synchronises-with is asymmetric for volatiles.

The JLS considers conflicting volatiles for data races, but this is only a remark on the DRF guarantee. See JMM mailing list posts #2477 to 2488.

9.2.1 Schedulers for deterministic small-step semantics

The default code equations for *Predicate.the* impose the type class constraint *eq* on the predicate elements. For the semantics, which contains the heap, there might be no such instance, so we use new constants for which other code equations can be used. These do not add the type class constraint, but may fail more often with non-uniqueness exception.

Fields

Problem: Does not terminate for cyclic class hierarchies! This problem already occurs in Jinja's well-formedness checker: *wf-cdecl* calls *wf-mdecl* before checking for acyclicity, but *wf-J-mdecl* involves the type judgements, which in turn requires *Fields* (via *sees-field*). Checking acyclicity before executing *Fields′* for tabulation is difficult because we would have to intertwine tabulation and well-formedness checking. Possible (local) solution: additional termination parameter (like memoisation for *rtranclp*) and list option as error return parameter.

9.8 An optimized JVM

```
theory JVMExec-Execute2
imports
  ../BV/BVNoTypeError
  ExternalCall-Execute
```

begin

This JVM must lookup the method declaration of the top call frame at every step to find the next instruction. It is more efficient to refine it such that the instruction list and the exception table are cached in the call frame. Even further, this theory adds keeps track of *drop pc ins*, whose head is the next instruction to execute.
