

# Jinja with Threads

Andreas Lochbihler

September 13, 2023

**Abstract.** We extend the Jinja source code semantics by Klein and Nipkow with Java-style arrays and threads. Concurrency is captured in a generic framework semantics for adding concurrency through interleaving to a sequential semantics, which features dynamic thread creation, inter-thread communication via shared memory, lock synchronisation and joins. Also, threads can suspend themselves and be notified by others. We instantiate the framework with the adapted versions of both Jinja source and byte code and show type safety for the multithreaded case. Equally, the compiler from source to byte code is extended, for which we prove weak bisimilarity between the source code small step semantics and the defensive Jinja virtual machine. On top of this, we formalise the JMM and show the DRF guarantee and consistency.

For description of the different parts, see [1, 2, 4, 3].

# Contents

<b>1</b>	<b>The generic multithreaded semantics</b>	<b>7</b>
1.1	State of the multithreaded semantics . . . . .	7
1.2	All about a managing a single lock . . . . .	17
1.3	Semantics of the thread actions for locking . . . . .	23
1.4	Semantics of the thread actions for thread creation . . . . .	27
1.5	Semantics of the thread actions for wait, notify and interrupt . . . . .	32
1.6	Semantics of the thread actions for purely conditional purpose such as Join . . . . .	36
1.7	Wellformedness conditions for the multithreaded state . . . . .	38
1.8	Semantics of the thread action ReleaseAcquire for the thread state . . . . .	42
1.9	Semantics of the thread actions for interruption . . . . .	43
1.10	The multithreaded semantics . . . . .	47
1.11	Auxiliary definitions for the progress theorem for the multithreaded semantics . . . . .	55
1.12	Deadlock formalisation . . . . .	61

*empty-ta*  $\equiv$  (*K* \$ [], [], [], [], [], [])

**notation** (*input*) *empty-ta* ( $\varepsilon$ )

Pretty syntax for specifying thread actions: Write  $\{ \text{Lock} \rightarrow l, \text{Unlock} \rightarrow l, \text{Suspend } w, \text{Interrupt } t \}$  instead of  $((K\$ []) (l \$:= [\text{Lock}, \text{Unlock}]), [], [\text{Suspend } w], [\text{Interrupt } t], [])$ .

*thread-action'* is a type that contains of all basic thread actions. Automatically coerce basic thread actions into that type and then dispatch to the right update function by pattern matching. For coercion, adhoc overloading replaces the generic injection *inject-thread-action* by the specific ones, i.e. constructors. To avoid ambiguities with observable actions, the

observable actions must be of sort *obs-action*, which the basic thread action types are not.

### 3.3.6 Code generation

New introduction rules for subcls1

**code-pred**

— Disallow mode *i-o-o* to force *code-pred* in subsequent predicates not to use this inefficient mode

(modes:  $i \Rightarrow i \Rightarrow i \Rightarrow \text{bool}$ ,  $i \Rightarrow i \Rightarrow o \Rightarrow \text{bool}$ )

subcls1

.

Introduce proper constant *subcls'* for *subcls* and generate executable equation for *subcls'*

**definition** *subcls'* **where** *subcls'* = *subcls*

**code-pred**

(modes:  $i \Rightarrow i \Rightarrow i \Rightarrow \text{bool}$ ,  $i \Rightarrow i \Rightarrow o \Rightarrow \text{bool}$ )

[inductify]

subcls'

.

**lemma** subcls-conv-subcls' [code-unfold]:

(subcls1 P)  $\hat{=}$  subcls' P

**by**(simp add: subcls'-def)

Change rule  $?P \vdash ?A[] \leq \text{Class Object}$  such that predicate compiler tests on class *Object* first. Otherwise *widen-i-o-i* never terminates.

**lemma** widen-array-object-code:

C = Object  $\Longrightarrow$  P  $\vdash$  Array A  $\leq$  Class C

**by**(auto intro: widen.intros)

**lemmas** [code-pred-intro] =

widen-refl widen-subcls widen-null widen-null-array widen-array-object-code widen-array-array

**code-pred**

(modes:  $i \Rightarrow i \Rightarrow i \Rightarrow \text{bool}$ )

widen

**by**(erule widen.cases) auto

Readjust the code equations for *widen* such that *widen-i-i-i* is guaranteed to contain () at most once (even in the code representation!). This is important for the scheduler and the small-step semantics because of the weaker code equations for *the*.

A similar problem cannot hit the subclass relation because, for acyclic subclass hierarchies, the paths in the hierarchy are unique and cycle-free.

**definition** *widen-i-i-i'* **where** *widen-i-i-i' = widen-i-i-i*

**declare** *widen.equation* [code del]

**lemmas** *widen-i-i-i'-equation* [code] = *widen.equation*[folded *widen-i-i-i'-def*]

**lemma** *widen-i-i-i-code* [code]:

*widen-i-i-i P T T' = (if P ⊢ T ≤ T' then Predicate.single () else bot)*

**by**(auto intro!: pred-eqI intro: widen-i-i-iI elim: widen-i-i-iE)

### 3.6 System Classes

**theory** *SystemClasses*

**imports**

*Exceptions*

**begin**

This theory provides definitions for the *Object* class, and the system exceptions.

Inline *SystemClasses* definition because they are polymorphic values that violate ML's value restriction.

*Object* has actually superclass, but we set it to the empty string for code generation. Any other class name (like *undefined*) would do as well except for code generation.

```

definition ObjectC :: 'm cdecl
where [code-unfold]:
  ObjectC =
    (Object, (STR "", [],
      [(wait, [], Void, Native),
       (notify, [], Void, Native),
       (notifyAll, [], Void, Native),
       (hashCode, [], Integer, Native),
       (clone, [], Class Object, Native),
       (print, [Integer], Void, Native),
       (currentThread, [], Class Thread, Native),
       (interrupted, [], Boolean, Native),
       (yield, [], Void, Native)
      ]))

```

```

definition ThrowableC :: 'm cdecl
where [code-unfold]: ThrowableC  $\equiv$  (Throwable, (Object, [], []))

```

```

definition NullPointerC :: 'm cdecl
where [code-unfold]: NullPointerC  $\equiv$  (NullPointer, (Throwable, [], []))

```

```

definition ClassCastC :: 'm cdecl
where [code-unfold]: ClassCastC  $\equiv$  (ClassCast, (Throwable, [], []))

```

```

definition OutOfMemoryC :: 'm cdecl
where [code-unfold]: OutOfMemoryC  $\equiv$  (OutOfMemory, (Throwable, [], []))

```

```

definition ArrayIndexOutOfBoundsC :: 'm cdecl
where [code-unfold]: ArrayIndexOutOfBoundsC  $\equiv$  (ArrayIndexOutOfBounds, (Throwable, [], []))

```

```

definition ArrayStoreC :: 'm cdecl
where [code-unfold]: ArrayStoreC  $\equiv$  (ArrayStore, (Throwable, [], []))

```

```

definition NegativeArraySizeC :: 'm cdecl

```

```

where [code-unfold]: NegativeArraySizeC  $\equiv$  (NegativeArraySize, (Throwable,[],[]))

Contrary to Sun's JVM 1.6.0\_07, cloning an interrupted thread does not yield an interrupted thread, because the interrupt flag is not stored inside the thread object. Starting a clone of a started thread with Sun JVM 1.6.0\_07 raises an illegal thread state exception, we just start another thread. The thread at <http://mail.openjdk.java.net/pipermail/core-libs-dev/2010-August/004715.html> discusses the general problem of thread cloning and argues against that. The bug report [http://bugs.sun.com/bugdatabase/view\\_bug.do?bug\\_id=6968584](http://bugs.sun.com/bugdatabase/view_bug.do?bug_id=6968584) changes the Thread class implementation such that `Object.clone()` can no longer be accessed for Thread and subclasses in Java 7.

Array cells are never volatile themselves.

 $\implies P, t \vdash \langle a.\text{join}(\lfloor \rfloor), h \rangle - \llbracket \text{Join } (\text{addr2thread-id } a), \text{IsInterrupted } t \ \text{False}, \text{ThreadJoin } (\text{addr2thread-id } a) \rrbracket \rightarrow \text{ext} \langle \text{RetVal Unit}, h \rangle$

| *RedJoinInterrupt*:

$\llbracket \text{typeof-addr } h \ a = \lfloor \text{Class-type } C \rfloor; P \vdash C \preceq^* \text{Thread} \rrbracket$   
 $\implies P, t \vdash \langle a.\text{join}(\lfloor \rfloor), h \rangle - \llbracket \text{IsInterrupted } t \ \text{True}, \text{ClearInterrupt } t, \text{ObsInterrupted } t \rrbracket \rightarrow \text{ext} \langle \text{RetEXC InterruptedException}, h \rangle$

— Interruption should produce inter-thread actions (JLS 17.4.4) for the synchronizes-with order. They should synchronize with the inter-thread actions that determine whether a thread has been interrupted. Hence, interruption generates an *ObsInterrupt* action.

Although *WakeUp* causes the interrupted thread to raise an *InterruptedException* independent of the interrupt status, the interrupt flag must be set with *Interrupt* such that other threads observe the interrupted thread as interrupted while it competes for the monitor lock again.

Interrupting a thread which has not yet been started does not set the interrupt flag (tested with Sun HotSpot JVM 1.6.0\_07).

| *RedInterrupt*:

$\llbracket \text{typeof-addr } h \ a = \lfloor \text{Class-type } C \rfloor; P \vdash C \preceq^* \text{Thread} \rrbracket$   
 $\implies P, t \vdash \langle a.\text{interrupt}(\lfloor \rfloor), h \rangle$   
 $\quad - \llbracket \text{ThreadExists } (\text{addr2thread-id } a) \ \text{True}, \text{WakeUp } (\text{addr2thread-id } a),$   
 $\quad \text{Interrupt } (\text{addr2thread-id } a), \text{ObsInterrupt } (\text{addr2thread-id } a) \rrbracket \rightarrow \text{ext}$   
 $\quad \langle \text{RetVal Unit}, h \rangle$

| *RedInterruptInexist*:

$\llbracket \text{typeof-addr } h \ a = \lfloor \text{Class-type } C \rfloor; P \vdash C \preceq^* \text{Thread} \rrbracket$   
 $\implies P, t \vdash \langle a.\text{interrupt}(\lfloor \rfloor), h \rangle$   
 $\quad - \llbracket \text{ThreadExists } (\text{addr2thread-id } a) \ \text{False} \rrbracket \rightarrow \text{ext}$   
 $\quad \langle \text{RetVal Unit}, h \rangle$

| *RedIsInterruptedTrue*:

$\llbracket \text{typeof-addr } h \ a = \lfloor \text{Class-type } C \rfloor; P \vdash C \preceq^* \text{Thread} \rrbracket$   
 $\implies P, t \vdash \langle a.\text{isInterrupted}(\lfloor \rfloor), h \rangle - \llbracket \text{IsInterrupted } (\text{addr2thread-id } a) \ \text{True}, \text{ObsInterrupted } (\text{addr2thread-id } a) \rrbracket \rightarrow \text{ext}$   
 $\quad \langle \text{RetVal (Bool True)}, h \rangle$

| *RedIsInterruptedFalse*:

$\llbracket \text{typeof-addr } h \ a = \lfloor \text{Class-type } C \rfloor; P \vdash C \preceq^* \text{Thread} \rrbracket$   
 $\implies P, t \vdash \langle a.\text{isInterrupted}(\lfloor \rfloor), h \rangle - \llbracket \text{IsInterrupted } (\text{addr2thread-id } a) \ \text{False} \rrbracket \rightarrow \text{ext} \langle \text{RetVal (Bool False)}, h \rangle$

— The JLS leaves unspecified whether *wait* first checks for the monitor state (whether the thread holds a lock on the monitor) or for the interrupt flag of the current thread. Sun Hotspot JVM 1.6.0\_07 seems to check for the monitor state first, so we do it here, too.

| *RedWaitInterrupt*:

$P, t \vdash \langle a.\text{wait}(\lfloor \rfloor), h \rangle - \llbracket \text{Unlock} \rightarrow a, \text{Lock} \rightarrow a, \text{IsInterrupted } t \ \text{True}, \text{ClearInterrupt } t, \text{ObsInterrupted } t \rrbracket \rightarrow \text{ext}$   
 $\quad \langle \text{RetEXC InterruptedException}, h \rangle$

| *RedWait*:

$P, t \vdash \langle a \cdot \text{wait}(\square), h \rangle - \llbracket \text{Suspend } a, \text{Unlock} \rightarrow a, \text{Lock} \rightarrow a, \text{ReleaseAcquire} \rightarrow a, \text{IsInterrupted } t \text{ False}, \text{SyncUnlock } a \rrbracket \rightarrow \text{ext} \langle \text{RetStaySame}, h \rangle$

| *RedWaitFail*:

$P, t \vdash \langle a \cdot \text{wait}(\square), h \rangle - \llbracket \text{UnlockFail} \rightarrow a \rrbracket \rightarrow \text{ext} \langle \text{RetEXC IllegalMonitorState}, h \rangle$

| *RedWaitNotified*:

$P, t \vdash \langle a \cdot \text{wait}(\square), h \rangle - \llbracket \text{Notified} \rrbracket \rightarrow \text{ext} \langle \text{RetVal Unit}, h \rangle$

— This rule does NOT check that the interrupted flag is set, but still clears it. The semantics will be that only the executing thread clears its interrupt.

| *RedWaitInterrupted*:

$P, t \vdash \langle a \cdot \text{wait}(\square), h \rangle - \llbracket \text{WokenUp}, \text{ClearInterrupt } t, \text{ObsInterrupted } t \rrbracket \rightarrow \text{ext} \langle \text{RetEXC InterruptedException}, h \rangle$

— Calls to wait may decide to immediately wake up spuriously. This is indistinguishable from waking up spuriously any time before being notified or interrupted. Spurious wakeups are configured by the *spurious-wakeup* parameter of the *heap-base* locale.

| *RedWaitSpurious*:

$\text{spurious-wakeups} \implies$

$P, t \vdash \langle a \cdot \text{wait}(\square), h \rangle - \llbracket \text{Unlock} \rightarrow a, \text{Lock} \rightarrow a, \text{ReleaseAcquire} \rightarrow a, \text{IsInterrupted } t \text{ False}, \text{SyncUnlock } a \rrbracket \rightarrow \text{ext} \langle \text{RetVal Unit}, h \rangle$

— *notify* and *notifyAll* do not perform synchronization inter-thread actions because they only tests whether the thread holds a lock, but do not change the lock state.

| *RedNotify*:

$P, t \vdash \langle a \cdot \text{notify}(\square), h \rangle - \llbracket \text{Notify } a, \text{Unlock} \rightarrow a, \text{Lock} \rightarrow a \rrbracket \rightarrow \text{ext} \langle \text{RetVal Unit}, h \rangle$

### 3.12 Generic Well-formedness of programs

```
theory WellForm
imports
  SystemClasses
  ExternalCall
begin
```

This theory defines global well-formedness conditions for programs but does not look inside method bodies. Hence it works for both Jinja and JVM programs. Well-typing of expressions is defined elsewhere (in theory *WellType*).

Because JinjaThreads does not have method overloading, its policy for method overriding is the classical one: *covariant in the result type but contravariant in the argument types*. This means the result type of the overriding method becomes more specific, the argument types become more general.

**type-synonym** *'m wf-mdecl-test* = *'m prog*  $\Rightarrow$  *cname*  $\Rightarrow$  *'m mdecl*  $\Rightarrow$  *bool*

**by**(simp)

Locking mechanism: The expression on which the thread is synchronized is evaluated first to a value. If this expression evaluates to null, a null pointer expression is thrown. If this expression evaluates to an address, a lock must be obtained on this address, the sync expression is rewritten to insync. For insync expressions, the body expression may be evaluated. If the body expression is only a value or a thrown exception, the lock is released and the synchronized expression reduces to the body's expression. This is the normal Java semantics, not the one as presented in LNCS 1523, Cenciarelli/Knapp/Reus/Wirsing. There the expression on which the thread synchronized is evaluated except for the last step. If the thread can obtain the lock on the object immediately after the last evaluation step, the evaluation is done and the lock acquired. If the lock cannot be obtained, the evaluation step is discarded. If another thread changes the evaluation result of this last step, the thread then will try to synchronize on the new object.

## Chapter 5

# Jinja Virtual Machine

### 5.1 State of the JVM

```
theory JVMState
imports
  ../Common/Observable-Events
begin
```

#### 5.1.1 Frame Stack

```
type-synonym
  pc = nat

type-synonym
  'addr frame = 'addr val list  $\times$  'addr val list  $\times$  cname  $\times$  mname  $\times$  pc
  — operand stack
  — registers (including this pointer, method parameters, and local variables)
  — name of class where current method is defined
  — parameter types
  — program counter within frame
```

```
print-translation <
  let
    fun tr'
      [Const (@{type-syntax list}, -) $ (Const (@{type-syntax val}, -) $ a1),
       Const (@{type-syntax prod}, -) $
         (Const (@{type-syntax list}, -) $ (Const (@{type-syntax val}, -) $ a2)) $
         (Const (@{type-syntax prod}, -) $
           Const (@{type-syntax String.literal}, -) $
             (Const (@{type-syntax prod}, -) $
               Const (@{type-syntax String.literal}, -) $
                 Const (@{type-syntax nat}, -)))] =
        if a1 = a2 then Syntax.const @{type-syntax frame} $ a1
        else raise Match;
      in [(@{type-syntax prod}, K tr')]
    end
  >
typ 'addr frame
```

### 5.1.2 Runtime State

**type-synonym**

$('addr, 'heap) \text{ jvm-state} = 'addr \text{ option} \times 'heap \times 'addr \text{ frame list}$   
 — exception flag, heap, frames

**type-synonym**

$'addr \text{ jvm-thread-state} = 'addr \text{ option} \times 'addr \text{ frame list}$   
 — exception flag, frames, thread lock state

**type-synonym**

## 6.5 BV Type Safety Proof

```

theory BVSpecTypeSafe
imports
  BVConform
  ../Common/ExternalCallWF
begin

```

```

declare listE-length [simp del]

```

This theory contains proof that the specification of the bytecode verifier only admits type safe programs.

### 6.5.1 Preliminaries

Simp and intro setup for the type safety proof:

```

context JVM-heap-conf-base begin

```

```

lemmas widen-rules [intro] = conf-widen confT-widen confs-widens confTs-widen

```

```

end

```

### 6.5.2 Exception Handling

For the *Invoke* instruction the BV has checked all handlers that guard the current *pc*.

**lemma** *Invoke-handlers*:

```

  match-ex-table P C pc xt = Some (pc',d')  $\implies$ 
   $\exists (f,t,D,h,d) \in \text{set } (\text{relevant-entries } P (\text{Invoke } n \ M) \ pc \ xt).$ 
   $(\text{case } D \text{ of } \text{None} \implies \text{True} \mid \text{Some } D' \implies P \vdash C \preceq^* D') \wedge pc \in \{f..<t\} \wedge pc' = h \wedge d' = d$ 
by (induct xt) (auto simp add: relevant-entries-def matches-ex-entry-def
  is-relevant-entry-def split: if-split-asm)

```

**lemma** *match-is-relevant*:

```

  assumes rv:  $\bigwedge D'. P \vdash D \preceq^* D' \implies \text{is-relevant-class } (ins \ ! \ i) \ P \ D'$ 
  assumes match: match-ex-table P D pc xt = Some (pc',d')
  shows  $\exists (f,t,D',h,d) \in \text{set } (\text{relevant-entries } P (ins \ ! \ i) \ pc \ xt). (\text{case } D' \text{ of } \text{None} \implies \text{True} \mid \text{Some } D''$

```

The next theorem collects the results of the sections above, i.e. exception handling and the execution step for each instruction. It states type safety for single step execution: in welltyped programs, a conforming state is transformed into another conforming state when one instruction is executed.
