Jinja with Threads

Andreas Lochbihler

March 17, 2025

Abstract. We extend the Jinja source code semantics by Klein and Nipkow with Java-style arrays and threads. Concurrency is captured in a generic framework semantics for adding concurrency through interleaving to a sequential semantics, which features dynamic thread creation, inter-thread communication via shared memory, lock synchronisation and joins. Also, threads can suspend themselves and be notified by others. We instantiate the framework with the adapted versions of both Jinja source and byte code and show type safety for the multithreaded case. Equally, the compiler from source to byte code is extended, for which we prove weak bisimilarity between the source code small step semantics and the defensive Jinja virtual machine. On top of this, we formalise the JMM and show the DRF guarantee and consistency.

For description of the different parts, see [1, 2, 4, 3].

Pretty syntax for specifying thread actions: Write ⦃ *Lock→l*, *Unlock→l*, *Suspend w*, *Interrupt t*⦄ instead of ((*K*$ [])(*l* $:= [*Lock*, *Unlock*]), [], [*Suspend w*], [*Interrupt t*], []).

thread-action' is a type that contains of all basic thread actions. Automatically coerce basic thread actions into that type and then dispatch to the right update function by pattern matching. For coercion, adhoc overloading replaces the generic injection *inject-thread-action*

by the specific ones, i.e. constructors. To avoid ambiguities with observable actions, the observable actions must be of sort *obs-action*, which the basic thread action types are not.

3.3.6 Code generation

New introduction rules for subcls1

code-pred
— Disallow mode *i-o-o* to force *code-pred* in subsequent predicates not to use this inefficient mode
(*modes*: *i* ⇒ *i* ⇒ *i* ⇒ *bool*, *i* ⇒ *i* ⇒ *o* ⇒ *bool*)
subcls1
.

Introduce proper constant *subcls'* for *subcls* and generate executable equation for *subcls'*

definition *subcls'* **where** *subcls'* = *subcls*

code-pred
(*modes*: *i* ⇒ *i* ⇒ *i* ⇒ *bool*, *i* ⇒ *i* ⇒ *o* ⇒ *bool*)
[*inductify*]
subcls'
.

lemma *subcls-conv-subcls'* [*code-unfold*]:
(*subcls1 P*)^**** = *subcls' P*
by(*simp add*: *subcls'-def*)

Change rule *?P* ⊢ *?A*⌊⌋ ≤ *Class Object* such that predicate compiler tests on class *Object* first. Otherwise *widen-i-o-i* never terminates.

lemma *widen-array-object-code*:
C = *Object* ⟹ *P* ⊢ *Array A* ≤ *Class C*
by(*auto intro*: *widen.intros*)

lemmas [*code-pred-intro*] =
widen-refl widen-subcls widen-null widen-null-array widen-array-object-code widen-array-array
code-pred
(*modes*: *i* ⇒ *i* ⇒ *i* ⇒ *bool*)
widen
by(*erule widen.cases*) *auto*

Readjust the code equations for *widen* such that *widen-i-i-i* is guaranteed to contain () at most once (even in the code representation!). This is important for the scheduler and the small-step semantics because of the weaker code equations for *the*.

A similar problem cannot hit the subclass relation because, for acyclic subclass hierarchies, the paths in the hieararchy are unique and cycle-free.

3.6 System Classes

theory *SystemClasses*
imports
Exceptions
begin

This theory provides definitions for the *Object* class, and the system exceptions.

Inline SystemClasses definition because they are polymorphic values that violate ML's value restriction.

Object has actually superclass, but we set it to the empty string for code generation. Any other class name (like *undefined*) would do as well except for code generation.

definition *ObjectC* :: *'m cdecl*

Contrary to Sun's JVM 1.6.0_07, cloning an interrupted thread does not yield an interrupted thread, because the interrupt flag is not stored inside the thread object. Starting a clone of a started thread with Sun JVM 1.6.0_07 raises an illegal thread state exception, we just start another thread. The thread at http://mail.openjdk.java.net/pipermail/core-libs-dev/2010-August/004715.html discusses the general problem of thread cloning and argues against that. The bug report http://bugs.sun.com/bugdatabase/view_bug.do?bug_id=6968584 changes the Thread class implementation such that `Object.clone()` can no longer be accessed for Thread and subclasses in Java 7.

Array cells are never volatile themselves.

— Interruption should produce inter-thread actions (JLS 17.4.4) for the synchronizes-with order. They should synchronize with the inter-thread actions that determine whether a thread has been interrupted. Hence, interruption generates an *ObsInterrupt* action.
Although *WakeUp* causes the interrupted thread to raise an *InterruptedException* independent of the interrupt status, the interrupt flag must be set with *Interrupt* such that other threads observe the interrupted thread as interrupted while it competes for the monitor lock again.
Interrupting a thread which has not yet been started does not set the interrupt flag (tested with Sun HotSpot JVM 1.6.0_07).

| *RedInterrupt*:
$[\![$ *typeof-addr* $h\ a = \lfloor$*Class-type* $C\rfloor$; $P \vdash C \preceq^*$ *Thread* $]\!]$
$\Longrightarrow P,t \vdash \langle a{\cdot}interrupt([]),\ h\rangle$
$-\{\!|$*ThreadExists* (*addr2thread-id* a) *True*, *WakeUp* (*addr2thread-id* a),

— The JLS leaves unspecified whether *wait* first checks for the monitor state (whether the thread holds a lock on the monitor) or for the interrupt flag of the current thread. Sun Hotspot JVM 1.6.0_07 seems to check for the monitor state first, so we do it here, too.
| *RedWaitInterrupt*:
$P,t \vdash \langle a{\cdot}wait([]),\ h\rangle\ -\{\!|$*Unlock*$\rightarrow a$, *Lock*$\rightarrow a$, *IsInterrupted* t *True*, *ClearInterrupt* t, *ObsInterrupted* $t|\!\}\rightarrow ext$
$\langle$*RetEXC InterruptedException*, $h\rangle$

| *RedWait*:

$P,t \vdash \langle a{\cdot}wait([]),\ h\rangle\ -\{\!|Suspend\ a,\ Unlock{\rightarrow}a,\ Lock{\rightarrow}a,\ ReleaseAcquire{\rightarrow}a,\ IsInterrupted\ t\ False,\ SyncUnlock\ a\ |\!\}{\rightarrow}ext$
$\langle RetStaySame,\ h\rangle$

| *RedWaitFail*:
$P,t \vdash \langle a{\cdot}wait([]),\ h\rangle\ -\{\!|UnlockFail{\rightarrow}a|\!\}{\rightarrow}ext\ \langle RetEXC\ IllegalMonitorState,\ h\rangle$

| *RedWaitNotified*:
$P,t \vdash \langle a{\cdot}wait([]),\ h\rangle\ -\{\!|Notified|\!\}{\rightarrow}ext\ \langle RetVal\ Unit,\ h\rangle$

— This rule does NOT check that the interrupted flag is set, but still clears it. The semantics will be that only the executing thread clears its interrupt.
| *RedWaitInterrupted*:
$P,t \vdash \langle a{\cdot}wait([]),\ h\rangle\ -\{\!|WokenUp,\ ClearInterrupt\ t,\ ObsInterrupted\ t|\!\}{\rightarrow}ext\ \langle RetEXC\ InterruptedException,\ h\rangle$

— Calls to wait may decide to immediately wake up spuriously. This is indistinguishable from waking up spuriously any time before being notified or interrupted. Spurious wakeups are configured by the *spurious-wakeup* parameter of the *heap-base* locale.
| *RedWaitSpurious*:
spurious-wakeups $\Longrightarrow$
$P,t \vdash \langle a{\cdot}wait([]),\ h\rangle\ -\{\!|Unlock{\rightarrow}a,\ Lock{\rightarrow}a,\ ReleaseAcquire{\rightarrow}a,\ IsInterrupted\ t\ False,\ SyncUnlock\ a|\!\}\ {\rightarrow}ext$
$\langle RetVal\ Unit,\ h\rangle$

— *notify* and *notifyAll* do not perform synchronization inter-thread actions because they only tests whether the thread holds a lock, but do not change the lock state.

| *RedNotify*:
$P,t \vdash \langle a{\cdot}notify([]),\ h\rangle\ -\{\!|Notify\ a,\ Unlock{\rightarrow}a,\ Lock{\rightarrow}a|\!\}{\rightarrow}ext\ \langle RetVal\ Unit,\ h\rangle$

3.12 Generic Well-formedness of programs

theory *WellForm*
imports
SystemClasses
ExternalCall
begin

This theory defines global well-formedness conditions for programs but does not look inside method bodies. Hence it works for both Jinja and JVM programs. Well-typing of expressions is defined elsewhere (in theory *WellType*).

Because JinjaThreads does not have method overloading, its policy for method overriding is the classical one: *covariant in the result type but contravariant in the argument types.* This means the result type of the overriding method becomes more specific, the argument types become more general.

Locking mechanism: The expression on which the thread is synchronized is evaluated first to a value. If this expression evaluates to null, a null pointer expression is thrown. If this expression evaluates to an address, a lock must be obtained on this address, the sync expression is rewritten to insync. For insync expressions, the body expression may be evaluated. If the body expression is only a value or a thrown exception, the lock is released and the synchronized expression reduces to the body's expression. This is the normal Java semantics, not the one as presented in LNCS 1523, Cenciarelli/Knapp/Reus/Wirsing. There the expression on which the thread synchronized is evaluated except for the last step. If the thread can obtain the lock on the object immediately after the last evaluation step, the evaluation is done and the lock acquired. If the lock cannot be obtained, the evaluation step is discarded. If another thread changes the evaluation result of this last step, the thread then will try to synchronize on the new object.

6.3 The Bytecode Verifier

theory *BVSpec*
imports
Effect
begin

This theory contains a specification of the BV. The specification describes correct typings of method bodies; it corresponds to type *checking*.

definition *check-types* :: $'m\ prog \Rightarrow nat \Rightarrow nat \Rightarrow ty_i'\ err\ list \Rightarrow bool$
where
check-types P mxs mxl $\tau s \equiv$ *set* $\tau s \subseteq$ *states P mxs mxl*

— An instruction is welltyped if it is applicable and its effect
— is compatible with the type at all successor instructions:
definition *wt-instr* :: $['m\ prog,ty,nat,pc,ex\text{-}table,'addr\ instr,pc,ty_m] \Rightarrow bool$
($\langle$-,-,-,-,- $\vdash$ -,- :: -$\rangle$ [60,0,0,0,0,0,0,61] 60)
where
$P,T,mxs,mpc,xt \vdash i,pc :: \tau s \equiv$
app i P mxs T pc mpc xt ($\tau s!pc$) $\wedge$
$(\forall (pc',\tau') \in$ *set* (*eff i P pc xt* ($\tau s!pc$)). $P \vdash \tau' \leq' \tau s!pc')$

— The type at *pc=0* conforms to the method calling convention:
definition *wt-start* :: $['m\ prog,cname,ty\ list,nat,ty_m] \Rightarrow bool$
where
wt-start P C Ts mxl_0 $\tau s \equiv$
$P \vdash$ *Some* ([],*OK* (*Class C*)#*map OK Ts*@*replicate* mxl_0 *Err*) $\leq' \tau s!0$

— A method is welltyped if the body is not empty,
— if the method type covers all instructions and mentions
— declared classes only, if the method calling convention is respected, and
— if all instructions are welltyped.
definition *wt-method* :: $['m\ prog,cname,ty\ list,ty,nat,nat,'addr\ instr\ list,\ ex\text{-}table,ty_m] \Rightarrow bool$
where
wt-method P C Ts T_r *mxs* mxl_0 *is xt* $\tau s \equiv$
0 $<$ *size is* $\wedge$ *size* τs = *size is* $\wedge$
check-types P mxs (*1*+*size Ts*+mxl_0) (*map OK* τs) $\wedge$
wt-start P C Ts mxl_0 τs $\wedge$

6.5.3 Single Instructions

In this subsection we prove for each single (welltyped) instruction that the state after execution of the instruction still conforms. Since we have already handled raised exceptions above, we can now assume that no exception has been raised in this step.

```

The next theorem collects the results of the sections above, i.e. exception handling and the execution step for each instruction. It states type safety for single step execution: in welltyped programs, a conforming state is transformed into another conforming state when one instruction is executed.

```
theorem instr-correct:
