

Lifting Definition Option*

René Thiemann

April 19, 2020

Abstract

We implemented a command, **lift-definition-option**, which can be used to easily generate elements of a restricted type $\{x :: 'a. P\ x\}$, provided the definition is of the form $\lambda y_1 \dots y_n. \text{if check } y_1 \dots y_n \text{ then Some (generate } y_1 \dots y_n :: 'a) \text{ else None}$ and $\text{check } y_1 \dots y_n \implies P \text{ (generate } y_1 \dots y_n)$ can be proven.

In principle, such a definition is also directly possible using one invocation of **lift-definition**. However, then this definition will not be suitable for code-generation. To this end, we automated a more complex construction of Joachim Breitner which is amenable for code-generation, and where the test $\text{check } y_1 \dots y_n$ will only be performed once. In the automation, one auxiliary type is created, and Isabelle's lifting- and transfer-package is invoked several times.

This entry is outdated as in the meantime the lifting- and transfer-package has the desired functionality in an even more general way. Therefore, only the examples are kept.

1 Examples

1.1 A simple restricted type without type-parameters

```
typedef restricted = { i :: int. i mod 2 = 0 } morphisms base restricted
  ⟨proof⟩
setup-lifting type-definition-restricted
```

Let us start with just using a sufficient criterion for testing for even numbers, without actually generating them, i.e., where the generator is just the identity function.

```
lift-definition(code-dt) restricted-of-simple :: int ⇒ restricted option is
  λ x :: int. if x ∈ {0, 2, 4, 6} then Some x else None ⟨proof⟩
```

We can also take several input arguments for the test, and generate a more complex value.

```
lift-definition(code-dt) restricted-of-many-args :: nat ⇒ int ⇒ bool ⇒ restricted
option is
  λ x y (b :: bool). if int x + y = 5 then Some ((int x + 1) * (y + 1)) else None
⟨proof⟩
```

No problem to use type parameters.

```
lift-definition(code-dt) restricted-of-poly :: 'b list ⇒ restricted option is
  λ xs :: 'b list. if length xs = 2 then Some (int (length (xs))) else None ⟨proof⟩
```

1.2 Examples with type-parameters in the restricted type.

```
typedef 'f restrictedf = { xs :: 'f list. length xs < 3 } morphisms basef restrictedf
  ⟨proof⟩
setup-lifting type-definition-restrictedf
```

It does not matter, if we take the same or different type-parameters in the lift-definition.

```
lift-definition(code-dt) test1 :: 'g ⇒ nat ⇒ 'g restrictedf option is
  λ (e :: 'g) x. if x < 2 then Some (replicate x e) else None ⟨proof⟩
```

```
lift-definition(code-dt) test2 :: 'f ⇒ nat ⇒ 'f restrictedf option is
  λ (e :: 'f) x. if x < 2 then Some (replicate x e) else None ⟨proof⟩
```

Tests with multiple type-parameters.

```
typedef ('a,'f) restr = { (xs :: 'a list,ys :: 'f list) . length xs = length ys }
  morphisms base' restr
  ⟨proof⟩
setup-lifting type-definition-restr
```

```
lift-definition(code-dt) restr-of-pair :: 'g ⇒ 'e list ⇒ nat ⇒ nat ⇒ ('e,nat) restr
option is
  λ (z :: 'g) (xs :: 'e list) (y :: nat) n. if length xs = n then Some (xs,replicate n
y) else None
```

<proof>

1.3 Example from IsaFoR/CeTA

An argument filter is a mapping π from n-ary function symbols into lists of positions, i.e., where each position is between 0 and n-1. In IsaFoR, (Isabelle’s Formalization of Rewriting) and CeTA [1], the corresponding certifier for term rewriting related properties, this is modelled as follows, where a partial argument filter in a map is extended to a full one by means of an default filter.

```
typedef 'f af = { ( $\pi :: 'f \times nat \Rightarrow nat\ list$ ). ( $\forall f\ n.\ set\ (\pi\ (f,n)) \subseteq \{0 ..< n\}$ )}
```

```
morphisms af Abs-af <proof>
```

```
setup-lifting type-definition-af
```

```
type-synonym 'f af-impl = (('f  $\times$  nat)  $\times$  nat list)list
```

```
fun fun-of-map-fun :: ('a  $\Rightarrow$  'b option)  $\Rightarrow$  ('a  $\Rightarrow$  'b)  $\Rightarrow$  ('a  $\Rightarrow$  'b) where  
  fun-of-map-fun m f a = (case m a of Some b  $\Rightarrow$  b | None  $\Rightarrow$  f a)
```

```
lift-definition(code-dt) af-of :: 'f af-impl  $\Rightarrow$  'f af option is  
   $\lambda s :: 'f\ af\ impl.$  if ( $\forall\ fidx \in set\ s.$  ( $\forall\ i \in set\ (snd\ fidx).$   $i < snd\ (fst\ fidx)$ ))  
    then Some (fun-of-map-fun (map-of s) ( $\lambda (f,n).$  [0 ..< n])) else None  
<proof>
```

1.4 Code generation tests and derived theorems

```
export-code
```

```
  restricted-of-many-args
```

```
  restricted-of-simple
```

```
  restricted-of-poly
```

```
  test1
```

```
  test2
```

```
  restr-of-pair
```

```
  af-of
```

```
in Haskell
```

```
lemma restricted-of-simple-Some:
```

```
  restricted-of-simple x = Some r  $\implies$  base r = x
```

```
<proof>
```

```
end
```

Acknowledgements

We thank Andreas Lochbihler for pointing us to Joachim’s solution, and we thank Makarius Wenzel for explaining us, how we can go back from states to local theories within Isabelle/ML.
