Abstract

Lenses provide an abstract interface for manipulating data types through spatially-separated views. They are defined abstractly in terms of two functions, *get*, the return a value from the source type, and *put* that updates the value. We mechanise the underlying theory of lenses, in terms of an algebraic hierarchy of lenses, including well-behaved and very well-behaved lenses, each lens class being characterised by a set of lens laws. We also mechanise a lens algebra in Isabelle that enables their composition and comparison, so as to allow construction of complex lenses. This is accompanied by a large library of algebraic laws. Moreover we also show how the lens classes can be applied by instantiating them with a number of Isabelle data types. This theory development is based on our recent papers [6, 5], which show how lenses can be used to unify heterogeneous representations of state-spaces in formalised programs.

3 Core Lens Laws

theory *Lens-Laws*

imports

Two Interp

begin

3.1 Lens Signature

This theory introduces the signature of lenses and indentifies the core algebraic hierarchy of lens classes, including laws for well-behaved, very well-behaved, and bijective lenses [4, 2, 8].

record (*'a, 'b*) *lens* =
lens-get :: *'b* \Rightarrow *'a* (*<get>*)
lens-put :: *'b* \Rightarrow *'a* \Rightarrow *'b* (*<put>*)

type-notation

lens (**infixr** $\langle \Longrightarrow \rangle$ 0)

Alternative parameters ordering, inspired by Back and von Wright's refinement calculus [1], which similarly uses two functions to characterise updates to variables.

abbreviation (*input*) *lens-set* :: (*'a* \Longrightarrow *'b*) \Rightarrow *'a* \Rightarrow *'b* \Rightarrow *'b* (*<lset>*) **where**
lens-set \equiv ($\lambda X v s. put_X s v$)

A lens $X : V \Longrightarrow S$, for source type S and view type V , identifies V with a subregion of S [4, 3], as illustrated in Figure 1. The arrow denotes X and the hatched area denotes the subregion V it characterises. Transformations on V can be performed without affecting the parts of S outside the hatched area. The lens signature consists of a pair of functions $get_X : S \Rightarrow V$ that extracts a view from a source, and $put_X : S \Rightarrow V \Rightarrow S$ that updates a view within a given source.

named-theorems *lens-defs*

lens-source gives the set of constructible sources; that is those that can be built by putting a value into an arbitrary source.

definition *lens-source* :: (*'a* \Longrightarrow *'b*) \Rightarrow *'b* *set* (*<S1>*) **where**
lens-source $X = \{s. \exists v s'. s = put_X s' v\}$

A partial version of *lens-get*, which can be useful for partial lenses.

definition *lens-partial-get* :: ('a \implies 'b) \Rightarrow 'b \Rightarrow 'a option (\langle pget \rangle) **where**
lens-partial-get x s = (if s \in \mathcal{S}_x then Some (get_x s) else None)

abbreviation *some-source* :: ('a \implies 'b) \Rightarrow 'b (\langle src \rangle) **where**
some-source X \equiv (SOME s. s \in \mathcal{S}_X)

definition *lens-create* :: ('a \implies 'b) \Rightarrow 'a \Rightarrow 'b (\langle create \rangle) **where**
[*lens-defs*]: *create*_X v = *put*_X (src_X) v

Function *create*_X v creates an instance of the source type of X by injecting v as the view, and leaving the remaining context arbitrary.

definition *lens-update* :: ('a \implies 'b) \Rightarrow ('a \Rightarrow 'a) \Rightarrow ('b \Rightarrow 'b) (\langle update \rangle) **where**
[*lens-defs*]: *lens-update* X f σ = *put*_X σ (f (get_X σ))

The update function is analogous to the record update function which lifts a function on a view type to one on the source type.

definition *lens-obs-eq* :: ('b \implies 'a) \Rightarrow 'a \Rightarrow 'a \Rightarrow bool (**infix** \langle s \rangle 50) **where**
[*lens-defs*]: *s*_1 \simeq_X *s*_2 = (*s*_1 = *put*_X *s*_2 (get_X *s*_1))

This relation states that two sources are equivalent outside of the region characterised by lens X.

definition *lens-override* :: ('b \implies 'a) \Rightarrow 'a \Rightarrow 'a \Rightarrow 'a (**infixl** \langle o \rangle 95) **where**
[*lens-defs*]: *S*_1 \triangleleft_X *S*_2 = *put*_X *S*_1 (get_X *S*_2)

abbreviation (*input*) *lens-override'* :: 'a \Rightarrow 'a \Rightarrow ('b \implies 'a) \Rightarrow 'a (\langle - \oplus_L - on \rightarrow [95,0,96] 95) **where**
*S*_1 \oplus_L *S*_2 on X \equiv *S*_1 \triangleleft_X *S*_2

Lens override uses a lens to replace part of a source type with a given value for the corresponding view.

3.2 Weak Lenses

Weak lenses are the least constrained class of lenses in our algebraic hierarchy. They simply require that the PutGet law [3, 2] is satisfied, meaning that *get* is the inverse of *put*.

locale *weak-lens* =

fixes x :: 'a \implies 'b (**structure**)

assumes *put-get*: *get* (*put* σ v) = v

begin

lemma *source-nonempty*: \exists s. s \in \mathcal{S}

by (*auto simp add: lens-source-def*)

lemma *put-closure*: *put* σ v \in \mathcal{S}

by (*auto simp add: lens-source-def*)

lemma *create-closure*: *create* v \in \mathcal{S}

by (*simp add: lens-create-def put-closure*)

lemma *src-source* [*simp*]: *src* \in \mathcal{S}

using *some-in-eq source-nonempty* **by** *auto*

lemma *create-get*: *get* (*create* v) = v

by (*simp add: lens-create-def put-get*)

```

lemma create-inj: inj create
  by (metis create-get injI)

lemma get-update: get (update f  $\sigma$ ) = f (get  $\sigma$ )
  by (simp add: put-get lens-update-def)

lemma view-determination:
  assumes put  $\sigma$  u = put  $\rho$  v
  shows u = v
  by (metis assms put-get)

lemma put-inj: inj (put  $\sigma$ )
  by (simp add: injI view-determination)

```

end

```

declare weak-lens.put-get [simp]
declare weak-lens.create-get [simp]

```

```

lemma dom-pget: dom pgetx =  $\mathcal{S}_x$ 
  by (simp add: lens-partial-get-def dom-def)

```

3.3 Well-behaved Lenses

Well-behaved lenses add to weak lenses that requirement that the GetPut law [3, 2] is satisfied, meaning that *put* is the inverse of *get*.

```

locale wb-lens = weak-lens +
  assumes get-put: put  $\sigma$  (get  $\sigma$ ) =  $\sigma$ 
begin

```

```

  lemma put-twice: put (put  $\sigma$  v) v = put  $\sigma$  v
    by (metis get-put put-get)

```

```

  lemma put-surjectivity:  $\exists \rho v. \text{put } \rho v = \sigma$ 
    using get-put by blast

```

```

  lemma source-stability:  $\exists v. \text{put } \sigma v = \sigma$ 
    using get-put by auto

```

```

  lemma source-UNIV [simp]:  $\mathcal{S} = \text{UNIV}$ 
    by (metis UNIV-eq-I put-closure wb-lens.source-stability wb-lens-axioms)

```

end

```

declare wb-lens.get-put [simp]

```

```

lemma wb-lens-weak [simp]: wb-lens x  $\implies$  weak-lens x
  by (simp add: wb-lens-def)

```

3.4 Mainly Well-behaved Lenses

Mainly well-behaved lenses extend weak lenses with the PutPut law that shows how one put override a previous one.

```

locale mwb-lens = weak-lens +

```

assumes *put-put*: $put (put \sigma v) u = put \sigma u$
begin

lemma *update-comp*: $update f (update g \sigma) = update (f \circ g) \sigma$
by (*simp add: put-get put-put lens-update-def*)

Mainly well-behaved lenses give rise to a weakened version of the *get*–*put* law, where the source must be within the set of constructible sources.

lemma *weak-get-put*: $\sigma \in \mathcal{S} \implies put \sigma (get \sigma) = \sigma$
by (*auto simp add: lens-source-def put-get put-put*)

lemma *weak-source-determination*:
assumes $\sigma \in \mathcal{S} \varrho \in \mathcal{S} get \sigma = get \varrho put \sigma v = put \varrho v$
shows $\sigma = \varrho$
by (*metis assms put-put weak-get-put*)

lemma *weak-put-eq*:
assumes $\sigma \in \mathcal{S} get \sigma = k put \sigma u = put \varrho v$
shows $put \varrho k = \sigma$
by (*metis assms put-put weak-get-put*)

Provides s is constructible, then *get* can be uniquely determined from *put*

lemma *weak-get-via-put*: $s \in \mathcal{S} \implies get s = (THE v. put s v = s)$
by (*rule sym, auto intro!: the-equality weak-get-put, metis put-get*)

end

abbreviation (*input*) *partial-lens* \equiv *mwb-lens*

declare *mwb-lens.put-put* [*simp*]
declare *mwb-lens.weak-get-put* [*simp*]

lemma *mwb-lens-weak* [*simp*]:
 $mwb-lens x \implies weak-lens x$
by (*simp add: mwb-lens.axioms(1)*)

3.5 Very Well-behaved Lenses

Very well-behaved lenses combine all three laws, as in the literature [3, 2]. The same set of axioms can be found in Back and von Wright’s refinement calculus [1], though with different names for the functions.

locale *vwb-lens* = *wb-lens* + *mwb-lens*
begin

lemma *source-determination*:
assumes $get \sigma = get \varrho put \sigma v = put \varrho v$
shows $\sigma = \varrho$
by (*metis assms get-put put-put*)

lemma *put-eq*:
assumes $get \sigma = k put \sigma u = put \varrho v$
shows $put \varrho k = \sigma$
using *assms weak-put-eq*[*of* $\sigma k u \varrho v$] **by** (*simp*)

get can be uniquely determined from *put*

lemma *get-via-put*: $get\ s = (THE\ v.\ put\ s\ v = s)$
by (*simp add: weak-get-via-put*)

lemma *get-surj*: *surj get*
by (*metis put-get surjI*)

Observation equivalence is an equivalence relation.

lemma *lens-obs-equiv*: *equivp* (\simeq)
proof (*rule equivpI*)
show *reflp* (\simeq)
by (*rule reflpI, simp add: lens-obs-eq-def get-put*)
show *symp* (\simeq)
by (*rule sympI, simp add: lens-obs-eq-def, metis get-put put-put*)
show *transp* (\simeq)
by (*rule transpI, simp add: lens-obs-eq-def, metis put-put*)
qed

end

abbreviation (*input*) *total-lens* \equiv *vwb-lens*

lemma *vwb-lens-wb* [*simp*]: *vwb-lens* $x \implies$ *wb-lens* x
by (*simp add: vwb-lens-def*)

lemma *vwb-lens-mwb* [*simp*]: *vwb-lens* $x \implies$ *mwb-lens* x
using *vwb-lens-def* **by** *auto*

lemma *mwb-UNIV-src-is-vwb-lens*:
 \llbracket *mwb-lens* X ; $\mathcal{S}_X = UNIV$ $\rrbracket \implies$ *vwb-lens* X
using *vwb-lens-def wb-lens-axioms-def wb-lens-def* **by** *fastforce*

Alternative characterisation: a very well-behaved (i.e. total) lens is a mainly well-behaved (i.e. partial) lens whose source is the universe set.

lemma *vwb-lens-iff-mwb-UNIV-src*:
vwb-lens $X \longleftrightarrow$ (*mwb-lens* $X \wedge \mathcal{S}_X = UNIV$)
by (*meson mwb-UNIV-src-is-vwb-lens vwb-lens-def wb-lens.source-UNIV*)

3.6 Ineffectual Lenses

Ineffectual lenses can have no effect on the view type – application of the *put* function always yields the same source. They are thus, trivially, very well-behaved lenses.

locale *ief-lens* = *weak-lens* +
assumes *put-inef*: *put* $\sigma\ v = \sigma$
begin

lemma *ief-then-vwb*: *vwb-lens* x
proof
fix $\sigma\ v\ u$
show *put* σ (*get* σ) = σ
by (*simp add: put-inef*)
show *put* (*put* $\sigma\ v$) $u =$ *put* $\sigma\ u$
by (*simp add: put-inef*)
qed

by (*metis* *pbij-lens-axioms-def* *pbij-lens-def* *weak-lens.put-closure* *weak-lens.put-get*)

3.8 Bijective Lenses

Bijective lenses characterise the situation where the source and view type are equivalent: in other words the view type fully characterises the whole source type. It is often useful when the view type and source type are syntactically different, but nevertheless correspond precisely in terms of what they observe. Bijective lenses are formulated using the strong GetPut law [3, 2].

```

locale bij-lens = weak-lens +
  assumes strong-get-put: put  $\sigma$  (get  $\rho$ ) =  $\rho$ 
begin

```

```

sublocale pbij-lens

```

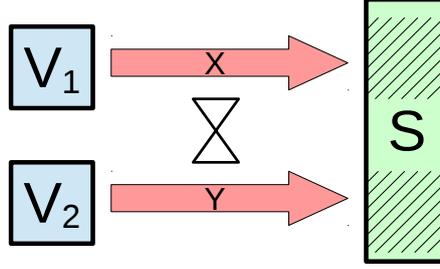

Figure 2: Lens Independence

using *pbij-vwb-is-bij-lens* by *auto*

3.9 Lens Independence

Lens independence shows when two lenses X and Y characterise disjoint regions of the source type, as illustrated in Figure 2. We specify this by requiring that the *put* functions of the two lenses commute, and that the *get* function of each lens is unaffected by application of *put* from the corresponding lens.

```

locale lens-indep =
  fixes  $X :: 'a \implies 'c$  and  $Y :: 'b \implies 'c$ 
  assumes lens-put-comm:  $put_X (put_Y \sigma v) u = put_Y (put_X \sigma u) v$ 
  and lens-put-irr1:  $get_X (put_Y \sigma v) = get_X \sigma$ 
  and lens-put-irr2:  $get_Y (put_X \sigma u) = get_Y \sigma$ 

```

notation *lens-indep* (**infix** $\langle \bowtie \rangle$ 50)

```

lemma lens-indepI:
   $\llbracket \bigwedge u v \sigma. put_x (put_y \sigma v) u = put_y (put_x \sigma u) v;$ 
   $\bigwedge v \sigma. get_x (put_y \sigma v) = get_x \sigma;$ 
   $\bigwedge u \sigma. get_y (put_x \sigma u) = get_y \sigma \rrbracket \implies x \bowtie y$ 
  by (simp add: lens-indep-def)

```

Lens independence is symmetric.

```

lemma lens-indep-sym:  $x \bowtie y \implies y \bowtie x$ 
  by (simp add: lens-indep-def)

```

```

lemma lens-indep-comm:
   $x \bowtie y \implies put_x (put_y \sigma v) u = put_y (put_x \sigma u) v$ 
  by (simp add: lens-indep-def)

```

```

lemma lens-indep-get [simp]:
  assumes  $x \bowtie y$ 
  shows  $get_x (put_y \sigma v) = get_x \sigma$ 
  using assms lens-indep-def by fastforce

```

Characterisation of independence for two very well-behaved lenses

```

lemma lens-indep-vwb-iff:
  assumes vwb-lens  $x$  vwb-lens  $y$ 
  shows  $x \bowtie y \iff (\forall u v \sigma. put_x (put_y \sigma v) u = put_y (put_x \sigma u) v)$ 

```

proof

```

assume  $x \bowtie y$ 
thus  $\forall u v \sigma. put_x (put_y \sigma v) u = put_y (put_x \sigma u) v$

3.10 Lens Compatibility

Lens compatibility is a weaker notion than independence. It allows that two lenses can overlap so long as they manipulate the source in the same way in that region. It is most easily defined in terms of a function for copying a region from one source to another using a lens.

definition *lens-compat* (**infix** $\langle \#\#_L \rangle$ 50) **where**
[lens-defs]: $\text{lens-compat } X Y = (\forall s_1 s_2. s_1 \triangleleft_X s_2 \triangleleft_Y s_2 = s_1 \triangleleft_Y s_2 \triangleleft_X s_2)$

lemma *lens-compat-idem* [*simp*]: $x \#\#_L x$
 by (*simp add: lens-defs*)

lemma *lens-compat-sym*: $x \#\#_L y \implies y \#\#_L x$
 by (*simp add: lens-defs*)

lemma *lens-indep-compat* [*simp*]: $x \bowtie y \implies x \#\#_L y$
 by (*simp add: lens-override-def lens-compat-def lens-indep-comm*)

end

4 Lens Algebraic Operators

```

theory Lens-Algebra
imports Lens-Laws
begin

```

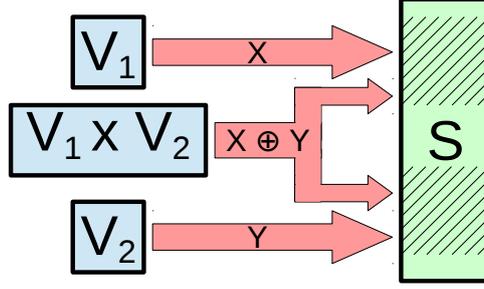

Figure 4: Lens Sum

4.1 Lens Composition, Plus, Unit, and Identity

We introduce the algebraic lens operators; for more information please see our paper [6]. Lens composition, illustrated in Figure 3, constructs a lens by composing the source of one lens with the view of another.

definition $lens-comp :: ('a \implies 'b) \Rightarrow ('b \implies 'c) \Rightarrow ('a \implies 'c)$ (**infixl** $\langle ;_L \rangle$ 80) **where**
 $[lens-defs]: lens-comp\ Y\ X = \langle \mid lens-get = get_Y \circ lens-get\ X$
 $, lens-put = (\lambda\ \sigma\ v.\ lens-put\ X\ \sigma\ (lens-put\ Y\ (lens-get\ X\ \sigma)\ v)) \mid \rangle$

Lens plus, as illustrated in Figure 4 parallel composes two independent lenses, resulting in a lens whose view is the product of the two underlying lens views.

definition $lens-plus :: ('a \implies 'c) \Rightarrow ('b \implies 'c) \Rightarrow 'a \times 'b \implies 'c$ (**infixr** $\langle +_L \rangle$ 75) **where**
 $[lens-defs]: X +_L Y = \langle \mid lens-get = (\lambda\ \sigma.\ (lens-get\ X\ \sigma,\ lens-get\ Y\ \sigma))$
 $, lens-put = (\lambda\ \sigma\ (u,\ v).\ lens-put\ X\ (lens-put\ Y\ \sigma\ v)\ u) \mid \rangle$

The product functor lens similarly parallel composes two lenses, but in this case the lenses have different sources and so the resulting source is also a product.

definition $lens-prod :: ('a \implies 'c) \Rightarrow ('b \implies 'd) \Rightarrow ('a \times 'b \implies 'c \times 'd)$ (**infixr** $\langle \times_L \rangle$ 85) **where**
 $[lens-defs]: lens-prod\ X\ Y = \langle \mid lens-get = map-prod\ get_X\ get_Y$
 $, lens-put = \lambda\ (u,\ v)\ (x,\ y).\ (put_X\ u\ x,\ put_Y\ v\ y) \mid \rangle$

The **fst** and **snd** lenses project the first and second elements, respectively, of a product source type.

definition $fst-lens :: 'a \implies 'a \times 'b$ ($\langle fst_L \rangle$) **where**
 $[lens-defs]: fst_L = \langle \mid lens-get = fst,\ lens-put = (\lambda\ (\sigma,\ \varrho)\ u.\ (u,\ \varrho)) \mid \rangle$

definition $snd-lens :: 'b \implies 'a \times 'b$ ($\langle snd_L \rangle$) **where**
 $[lens-defs]: snd_L = \langle \mid lens-get = snd,\ lens-put = (\lambda\ (\sigma,\ \varrho)\ u.\ (\sigma,\ u)) \mid \rangle$

lemma $get-fst-lens\ [simp]: get_{fst_L}\ (x,\ y) = x$
by ($simp\ add: fst-lens-def$)

lemma $get-snd-lens\ [simp]: get_{snd_L}\ (x,\ y) = y$
by ($simp\ add: snd-lens-def$)

The swap lens is a bijective lens which swaps over the elements of the product source type.

abbreviation $swap-lens :: 'a \times 'b \implies 'b \times 'a$ ($\langle swap_L \rangle$) **where**
 $swap_L \equiv snd_L +_L fst_L$

The zero lens is an ineffectual lens whose view is a unit type. This means the zero lens cannot distinguish or change the source type.

definition *zero-lens* :: $unit \implies 'a \langle 0_L \rangle$ **where**
[lens-defs]: $0_L = \langle lens-get = (\lambda -. ()), lens-put = (\lambda \sigma x. \sigma) \rangle$

The identity lens is a bijective lens where the source and view type are the same.

definition *id-lens* :: $'a \implies 'a \langle 1_L \rangle$ **where**
[lens-defs]: $1_L = \langle lens-get = id, lens-put = (\lambda -. id) \rangle$

The quotient operator $X /_L Y$ shortens lens X by cutting off Y from the end. It is thus the dual of the composition operator.

definition *lens-quotient* :: $('a \implies 'c) \Rightarrow ('b \implies 'c) \Rightarrow 'a \implies 'b$ (**infixr** $\langle '/_L \rangle 90$) **where**
[lens-defs]: $X /_L Y = \langle lens-get = \lambda \sigma. get_X (create_Y \sigma)$
 $, lens-put = \lambda \sigma v. get_Y (put_X (create_Y \sigma) v) \rangle$

Lens inverse take a bijective lens and swaps the source and view types.

definition *lens-inv* :: $('a \implies 'b) \Rightarrow ('b \implies 'a) \langle inv_L \rangle$ **where**
[lens-defs]: $lens-inv x = \langle lens-get = create_x, lens-put = \lambda \sigma. get_x \rangle$

4.2 Closure Properties

We show that the core lenses combinators defined above are closed under the key lens classes.

lemma *id-wb-lens*: $wb-lens\ 1_L$
by (*unfold-locales*, *simp-all add: id-lens-def*)

by (*simp add: lens-defs*)

lemma *lens-obs-eq-as-override*: $\text{vwb-lens } X \implies s_1 \simeq_X s_2 \iff (s_2 = s_1 \oplus_L s_2 \text{ on } X)$

by (auto simp add: lens-defs; metis vwb-lens.put-eq)

end

5 Order and Equivalence on Lenses

theory *Lens-Order*
 imports *Lens-Algebra*
 begin

5.1 Sub-lens Relation

A lens X is a sub-lens of Y if there is a well-behaved lens Z such that $X = Z;_L Y$, or in other words if X can be expressed purely in terms of Y .

definition *sublens* :: ($'a \implies 'c$) \implies ($'b \implies 'c$) \implies bool (**infix** $\langle \subseteq_L \rangle$ 55) **where**
 [*lens-defs*]: *sublens* $X Y = (\exists Z :: ('a, 'b) \text{ lens. } vwb\text{-lens } Z \wedge X = Z ;_L Y)$

Various lens classes are downward closed under the sublens relation.

lemma *sublens-pres-mwb*:
 $\llbracket mwb\text{-lens } Y; X \subseteq_L Y \rrbracket \implies mwb\text{-lens } X$
 by (*unfold-locales*, auto simp add: *sublens-def lens-comp-def*)

lemma *sublens-pres-wb*:
 $\llbracket wb\text{-lens } Y; X \subseteq_L Y \rrbracket \implies wb\text{-lens } X$
 by (*unfold-locales*, auto simp add: *sublens-def lens-comp-def*)

lemma *sublens-pres-vwb*:
 $\llbracket vwb\text{-lens } Y; X \subseteq_L Y \rrbracket \implies vwb\text{-lens } X$
 by (*unfold-locales*, auto simp add: *sublens-def lens-comp-def*)

Sublens is a preorder as the following two theorems show.

lemma *sublens-refl* [*simp*]:
 $X \subseteq_L X$
 using *id-vwb-lens sublens-def* by *fastforce*

lemma *sublens-trans* [*trans*]:
 $\llbracket X \subseteq_L Y; Y \subseteq_L Z \rrbracket \implies X \subseteq_L Z$
 apply (*auto simp add: sublens-def lens-comp-assoc*)
 apply (*rename-tac* $Z_1 Z_2$)
 apply (*rule-tac* $x=Z_1 ;_L Z_2$ in *exI*)
 apply (*simp add: lens-comp-assoc*)
 using *comp-vwb-lens* apply *blast*
 done

Sublens has a least element – 0_L – and a greatest element – 1_L . Intuitively, this shows that sublens orders how large a portion of the source type a particular lens views, with 0_L observing the least, and 1_L observing the most.

lemma *sublens-least*: $wb\text{-lens } X \implies 0_L \subseteq_L X$
 using *sublens-def unit-vwb-lens* by *fastforce*

lemma *sublens-greatest*: $vwb\text{-lens } X \implies X \subseteq_L 1_L$
 by (*simp add: sublens-def*)

If Y is a sublens of X then any put using X will necessarily erase any put using Y . Similarly, any two source types are observationally equivalent by Y when performed following a put using X .

lemma *sublens-put-put*:

$\llbracket \text{mwb-lens } X; Y \subseteq_L X \rrbracket \implies \text{put}_X (\text{put}_Y \sigma v) u = \text{put}_X \sigma u$
by (*auto simp add: sublens-def lens-comp-def*)

lemma *sublens-obs-get*:

$\llbracket \text{mwb-lens } X; Y \subseteq_L X \rrbracket \implies \text{get}_Y (\text{put}_X \sigma v) = \text{get}_Y (\text{put}_X \varrho v)$
by (*auto simp add: sublens-def lens-comp-def*)

Sublens preserves independence; in other words if Y is independent of Z , then also any X smaller than Y is independent of Z .

lemma *sublens-pres-indep*:

$\llbracket X \subseteq_L Y; Y \bowtie Z \rrbracket \implies X \bowtie Z$
apply (*auto intro!: lens-indepI simp add: sublens-def lens-comp-def lens-indep-comm*)
apply (*simp add: lens-indep-sym*)

done

lemma *sublens-pres-indep'*:

$\llbracket X \subseteq_L Y; Z \bowtie Y \rrbracket \implies Z \bowtie X$
by (*meson lens-indep-sym sublens-pres-indep*)

lemma *sublens-compat*: $\llbracket \text{vwb-lens } X; \text{vwb-lens } Y; X \subseteq_L Y \rrbracket \implies X \#\#_L Y$

unfolding *lens-compat-def lens-override-def*

by (*metis (no-types, opaque-lifting) sublens-obs-get sublens-put-put vwb-lens-mwb vwb-lens-wb wb-lens.get-put*)

Well-behavedness of lens quotient has sublens as a proviso. This is because we can only remove X from Y if X is smaller than Y .

lemma *lens-quotient-mwb*:

$\llbracket \text{mwb-lens } Y; X \subseteq_L Y \rrbracket \implies \text{mwb-lens } (X /_L Y)$
by (*unfold-locales, auto simp add: lens-quotient-def lens-create-def sublens-def lens-comp-def comp-def*)

5.2 Lens Equivalence

Using our preorder, we can also derive an equivalence on lenses as follows. It should be noted that this equality, like sublens, is heterogeneously typed – it can compare lenses whose view types are different, so long as the source types are the same. We show that it is reflexive, symmetric, and transitive.

definition *lens-equiv* :: $('a \implies 'c) \Rightarrow ('b \implies 'c) \Rightarrow \text{bool}$ (**infix** $\langle \approx_L \rangle$ 51) **where**

[*lens-defs*]: $\text{lens-equiv } X Y = (X \subseteq_L Y \wedge Y \subseteq_L X)$

lemma *lens-equivI* [*intro*]:

$\llbracket X \subseteq_L Y; Y \subseteq_L X \rrbracket \implies X \approx_L Y$
by (*simp add: lens-equiv-def*)

lemma *lens-equiv-refl* [*simp*]:

$X \approx_L X$
by (*simp add: lens-equiv-def*)

lemma *lens-equiv-sym*:

$X \approx_L Y \implies Y \approx_L X$
by (*simp add: lens-equiv-def*)

lemma *lens-equiv-trans* [*trans*]:
 $\llbracket X \approx_L Y; Y \approx_L Z \rrbracket \implies X \approx_L Z$
by (*auto intro: sublens-trans simp add: lens-equiv-def*)

lemma *lens-equiv-pres-indep*:
 $\llbracket X \approx_L Y; Y \bowtie Z \rrbracket \implies X \bowtie Z$
using *lens-equiv-def sublens-pres-indep* **by** *blast*

lemma *lens-equiv-pres-indep'*:
 $\llbracket X \approx_L Y; Z \bowtie Y \rrbracket \implies Z \bowtie X$
using *lens-equiv-def sublens-pres-indep'* **by** *blast*

lemma *lens-comp-cong-1*: $X \approx_L Y \implies X ;_L Z \approx_L Y ;_L Z$
unfolding *lens-equiv-def*
by (*metis (no-types, lifting) lens-comp-assoc sublens-def*)

5.3 Further Algebraic Laws

This law explains the behaviour of lens quotient.

lemma *lens-quotient-comp*:
 $\llbracket \text{weak-lens } Y; X \subseteq_L Y \rrbracket \implies (X /_L Y) ;_L Y = X$
by (*auto simp add: lens-quotient-def lens-comp-def comp-def sublens-def*)

Plus distributes through quotient.

lemma *lens-quotient-plus*:
 $\llbracket \text{mwb-lens } Z; X \subseteq_L Z; Y \subseteq_L Z \rrbracket \implies (X +_L Y) /_L Z = (X /_L Z) +_L (Y /_L Z)$
apply (*auto simp add: lens-quotient-def lens-plus-def sublens-def lens-comp-def comp-def*)
apply (*rule ext*)
apply (*rule ext*)
apply (*simp add: prod.case-eq-if*)
done

Laws for for lens plus on the denominator. These laws allow us to extract compositions of fst_L and snd_L terms.

lemma *lens-quotient-plus-den1*:
 $\llbracket \text{weak-lens } x; \text{weak-lens } y; x \bowtie y \rrbracket \implies x /_L (x +_L y) = \text{fst}_L$
by (*auto simp add: lens-defs prod.case-eq-if fun-eq-iff, metis (lifting) lens-indep-def weak-lens.put-get*)

lemma *lens-quotient-plus-den2*: $\llbracket \text{weak-lens } x; \text{weak-lens } z; x \bowtie z; y \subseteq_L z \rrbracket \implies y /_L (x +_L z) = (y /_L z) ;_L \text{snd}_L$
by (*auto simp add: lens-defs prod.case-eq-if fun-eq-iff lens-indep.lens-put-irr2*)

There follows a number of laws relating sublens and summation. Firstly, sublens is preserved by summation.

lemma *plus-pred-sublens*: $\llbracket \text{mwb-lens } Z; X \subseteq_L Z; Y \subseteq_L Z; X \bowtie Y \rrbracket \implies (X +_L Y) \subseteq_L Z$
apply (*auto simp add: sublens-def*)
apply (*rename-tac Z₁ Z₂*)
apply (*rule-tac x=Z₁ +_L Z₂ in exI*)
apply (*auto intro!: plus-wb-lens*)
apply (*simp add: lens-comp-indep-cong-left*)
apply (*simp add: plus-lens-distr*)
done

Intuitively, lens plus is associative. However we cannot prove this using HOL equality due to monomorphic typing of this operator. But since sublens and lens equivalence are both heterogeneous we can now prove this in the following three lemmas.

lemma *lens-plus-sub-assoc-1*:

```

 $X +_L Y +_L Z \subseteq_L (X +_L Y) +_L Z$ 
apply (simp add: sublens-def)
apply (rule-tac x=(fstL ;L fstL) +L (sndL ;L fstL) +L sndL in exI)
apply (auto)
apply (rule plus-vwb-lens)
  apply (simp add: comp-vwb-lens fst-vwb-lens)
  apply (rule plus-vwb-lens)
    apply (simp add: comp-vwb-lens fst-vwb-lens snd-vwb-lens)
    apply (simp add: snd-vwb-lens)
    apply (simp add: lens-indep-left-ext)
apply (rule lens-indep-sym)
apply (rule plus-pres-lens-indep)
  using fst-snd-lens-indep fst-vwb-lens lens-indep-left-comp lens-indep-sym vwb-lens-mwb apply blast
  using fst-snd-lens-indep lens-indep-left-ext lens-indep-sym apply blast
apply (auto simp add: lens-plus-def lens-comp-def fst-lens-def snd-lens-def prod.case-eq-if split-beta')[1]
done

```

lemma *lens-plus-sub-assoc-2*:

```

 $(X +_L Y) +_L Z \subseteq_L X +_L Y +_L Z$ 
apply (simp add: sublens-def)
apply (rule-tac x=(fstL +L (fstL ;L sndL)) +L (sndL ;L sndL) in exI)
apply (auto)
apply (rule plus-vwb-lens)
  apply (rule plus-vwb-lens)
    apply (simp add: fst-vwb-lens)
    apply (simp add: comp-vwb-lens fst-vwb-lens snd-vwb-lens)
    apply (rule lens-indep-sym)
    apply (rule lens-indep-left-ext)
    using fst-snd-lens-indep lens-indep-sym apply blast
    apply (auto intro: comp-vwb-lens simp add: snd-vwb-lens)
apply (rule plus-pres-lens-indep)
  apply (simp add: lens-indep-left-ext lens-indep-sym)
  apply (simp add: snd-vwb-lens)
apply (auto simp add: lens-plus-def lens-comp-def fst-lens-def snd-lens-def prod.case-eq-if split-beta')[1]
done

```

lemma *lens-plus-assoc*:

```

 $(X +_L Y) +_L Z \approx_L X +_L Y +_L Z$ 
by (simp add: lens-equivI lens-plus-sub-assoc-1 lens-plus-sub-assoc-2)

```

We can similarly show that it is commutative.

lemma *lens-plus-sub-comm*: $X \bowtie Y \implies X +_L Y \subseteq_L Y +_L X$

```

apply (simp add: sublens-def)
apply (rule-tac x=sndL +L fstL in exI)
apply (auto)
apply (simp add: fst-vwb-lens lens-indep-sym snd-vwb-lens)
apply (simp add: lens-indep-sym lens-plus-swap)
done

```

lemma *lens-plus-comm*: $X \bowtie Y \implies X +_L Y \approx_L Y +_L X$

```

by (simp add: lens-equivI lens-indep-sym lens-plus-sub-comm)

```

Any composite lens is larger than an element of the lens, as demonstrated by the following four laws.

lemma *lens-plus-ub* [*simp*]: $wb\text{-lens } Y \implies X \subseteq_L X +_L Y$
by (*metis fst-lens-plus fst-vwb-lens sublens-def*)

lemma *lens-plus-right-sublens*:
 $\llbracket vwb\text{-lens } Y; Y \bowtie Z; X \subseteq_L Z \rrbracket \implies X \subseteq_L Y +_L Z$
apply (*auto simp add: sublens-def*)
apply (*rename-tac Z'*)

5.4 Bijective Lens Equivalences

A bijective lens, like a bijective function, is its own inverse. Thus, if we compose its inverse with itself we get 1_L .

lemma *bij-lens-inv-left*:

bij-lens $X \implies \text{inv}_L X ;_L X = 1_L$

by (*auto simp add: lens-inv-def lens-comp-def lens-create-def comp-def id-lens-def, rule ext, auto*)

lemma *bij-lens-inv-right*:

bij-lens $X \implies X ;_L \text{inv}_L X = 1_L$

by (*auto simp add: lens-inv-def lens-comp-def comp-def id-lens-def, rule ext, auto*)

The following important results shows that bijective lenses are precisely those that are equivalent to identity. In other words, a bijective lens views all of the source type.

lemma *bij-lens-equiv-id*:

bij-lens $X \iff X \approx_L 1_L$

apply (*auto*)

apply (*rule lens-equivI*)

apply (*simp-all add: sublens-def*)

apply (*rule-tac x=lens-inv X in exI*)

apply (*simp add: bij-lens-inv-left lens-inv-bij*)

apply (*auto simp add: lens-equiv-def sublens-def id-lens-def lens-comp-def comp-def*)

apply (*unfold-locales*)

apply (*simp*)

apply (*simp*)

apply (*metis (no-types, lifting) vwb-lens-wb wb-lens-weak weak-lens.put-get*)

done

For this reason, by transitivity, any two bijective lenses with the same source type must be equivalent.

lemma *bij-lens-equiv*:

$\llbracket \text{bij-lens } X; X \approx_L Y \rrbracket \implies \text{bij-lens } Y$

by (*meson bij-lens-equiv-id lens-equiv-def sublens-trans*)

lemma *bij-lens-cong*:

$X \approx_L Y \implies \text{bij-lens } X = \text{bij-lens } Y$

by (*meson bij-lens-equiv lens-equiv-sym*)

We can also show that the identity lens 1_L is unique. That is to say it is the only lens which when compose with Y will yield Y .

lemma *lens-id-unique*:

weak-lens $Y \implies Y = X ;_L Y \implies X = 1_L$

apply (*cases Y*)

apply (*cases X*)

apply (*auto simp add: lens-comp-def comp-def id-lens-def fun-eq-iff*)

apply (*metis select-convs(1) weak-lens.create-get*)

apply (*metis select-convs(1) select-convs(2) weak-lens.put-get*)

done

Consequently, if composition of two lenses X and Y yields 1_L , then both of the composed lenses must be bijective.

lemma *bij-lens-via-comp-id-left*:
 $\llbracket \text{wb-lens } X; \text{wb-lens } Y; X ;_L Y = 1_L \rrbracket \implies \text{bij-lens } X$
apply (*cases* Y)
apply (*cases* X)
apply (*auto simp add: lens-comp-def comp-def id-lens-def fun-eq-iff*)
apply (*unfold-locales*)
apply (*simp-all*)
using *vwb-lens-wb wb-lens-weak weak-lens.put-get* **apply** *fastforce*
apply (*metis select-convs(1) select-convs(2) wb-lens-weak weak-lens.put-get*)
done

lemma *bij-lens-via-comp-id-right*:
 $\llbracket \text{wb-lens } X; \text{wb-lens } Y; X ;_L Y = 1_L \rrbracket \implies \text{bij-lens } Y$
apply (*cases* Y)
apply (*cases* X)
apply (*auto simp add: lens-comp-def comp-def id-lens-def fun-eq-iff*)
apply (*unfold-locales*)
apply (*simp-all*)
using *vwb-lens-wb wb-lens-weak weak-lens.put-get* **apply** *fastforce*
apply (*metis select-convs(1) select-convs(2) wb-lens-weak weak-lens.put-get*)
done

Importantly, an equivalence between two lenses can be demonstrated by showing that one lens can be converted to the other by application of a suitable bijective lens Z . This Z lens converts the view type of one to the view type of the other.

lemma *lens-equiv-via-bij*:
assumes *bij-lens* Z $X = Z ;_L Y$
shows $X \approx_L Y$
using *assms*
apply (*auto simp add: lens-equiv-def sublens-def*)
using *bij-lens-vwb* **apply** *blast*
apply (*rule-tac x=lens-inv Z in exI*)
apply (*auto simp add: lens-comp-assoc bij-lens-inv-left*)
using *bij-lens-vwb lens-inv-bij* **apply** *blast*
done

Indeed, we actually have a stronger result than this – the equivalent lenses are precisely those than can be converted to one another through a suitable bijective lens. Bijective lenses can thus be seen as a special class of "adapter" lenses.

lemma *lens-equiv-iff-bij*:
assumes *weak-lens* Y
shows $X \approx_L Y \iff (\exists Z. \text{bij-lens } Z \wedge X = Z ;_L Y)$
apply (*rule iffI*)
apply (*auto simp add: lens-equiv-def sublens-def lens-id-unique*)[1]

5.6 Alternative Sublens Characterisation

The following definition is equivalent to the above when the two lenses are very well behaved.

definition *sublens'* :: $(\prime a \implies \prime c) \Rightarrow (\prime b \implies \prime c) \Rightarrow \text{bool}$ (**infix** $\langle \subseteq_L' \rangle$ 55) **where**

[*lens-defs*]: *sublens'* $X Y = (\forall s_1 s_2 s_3. s_1 \oplus_L s_2$ on $Y \oplus_L s_3$ on $X = s_1 \oplus_L s_2 \oplus_L s_3$ on X on Y)

We next prove some characteristic properties of our alternative definition of sublens.

lemma *sublens'-prop1*:

assumes *vwb-lens* X $X \subseteq_L' Y$

shows $\text{put}_X (\text{put}_Y s_1 (\text{get}_Y s_2)) s_3 = \text{put}_Y s_1 (\text{get}_Y (\text{put}_X s_2 s_3))$

using *assms*

by (*simp add: sublens'-def, metis lens-override-def mwb-lens-def vwb-lens-mwb weak-lens.put-get*)

lemma *sublens'-prop2*:

assumes *vwb-lens* X $X \subseteq_L' Y$

shows $\text{get}_X (\text{put}_Y s_1 (\text{get}_Y s_2)) = \text{get}_X s_2$

using *assms unfolding sublens'-def*

by (*metis lens-override-def vwb-lens-wb wb-lens-axioms-def wb-lens-def weak-lens.put-get*)

lemma *sublens'-prop3*:

assumes *vwb-lens* X *vwb-lens* Y $X \subseteq_L' Y$

shows $\text{put}_Y \sigma (\text{get}_Y (\text{put}_X (\text{put}_Y \varrho (\text{get}_Y \sigma)) v)) = \text{put}_X \sigma v$

by (*metis assms(1) assms(2) assms(3) mwb-lens-def sublens'-prop1 vwb-lens.put-eq vwb-lens-mwb weak-lens.put-get*)

Finally we show our two definitions of sublens are equivalent, assuming very well behaved lenses.

lemma *sublens'-implies-sublens*:

assumes *vwb-lens* X *vwb-lens* Y $X \subseteq_L' Y$

shows $X \subseteq_L Y$

7 Scenes

```
theory Scenes
  imports Lens-Symmetric
```

begin

Like lenses, scenes characterise a region of a source type. However, unlike lenses, scenes do not explicitly assign a view type to this region, and consequently they have just one type parameter. This means they can be more flexibly composed, and in particular it is possible to show they form nice algebraic structures in Isabelle/HOL. They are mainly of use in characterising sets of variables, where, of course, we do not care about the types of those variables and therefore representing them as lenses is inconvenient.

7.1 Overriding Functions

Overriding functions provide an abstract way of replacing a region of an existing source with the corresponding region of another source.

```
locale overrider =  
  fixes  $F :: 's \Rightarrow 's \Rightarrow 's$  (infixl  $\langle \triangleright \rangle$  65)  
  assumes  
    ovr-overshadow-left:  $x \triangleright y \triangleright z = x \triangleright z$  and  
    ovr-overshadow-right:  $x \triangleright (y \triangleright z) = x \triangleright z$   
begin  
  lemma ovr-assoc:  $x \triangleright (y \triangleright z) = x \triangleright y \triangleright z$   
    by (simp add: ovr-overshadow-left ovr-overshadow-right)  
end
```

```
locale idem-overrider = overrider +  
  assumes ovr-idem:  $x \triangleright x = x$ 
```

```
declare overrider.ovr-overshadow-left [simp]  
declare overrider.ovr-overshadow-right [simp]  
declare idem-overrider.ovr-idem [simp]
```

7.2 Scene Type

```
typedef  $'s$  scene =  $\{F :: 's \Rightarrow 's \Rightarrow 's. \text{overrider } F\}$   
  by (rule-tac  $x=\lambda x y. x$  in exI, simp, unfold-locales, simp-all)
```

```
setup-lifting type-definition-scene
```

```
lift-definition idem-scene ::  $'s$  scene  $\Rightarrow$  bool is idem-overrider .
```

```

keywords *alphabet statespace :: thy-defn*

begin

In this section we define a number of concrete instantiations of the lens locales, including functions lenses, list lenses, and record lenses.

9.1 Function Lens

A function lens views the valuation associated with a particular domain element $'a$. We require that range type of a lens function has cardinality of at least 2; this ensures that properties of independence are provable.

definition *fun-lens* :: $'a \Rightarrow ('b::two \implies ('a \Rightarrow 'b))$ **where**

[*lens-defs*]: *fun-lens x* = (\llbracket *lens-get* = $(\lambda f. f x)$, *lens-put* = $(\lambda f u. f(x := u))$ \rrbracket)

lemma *fun-vwb-lens: vwb-lens (fun-lens x)*

by (*unfold-locales*, *simp-all add: fun-lens-def*)

Two function lenses are independent if and only if the domain elements are different.

lemma *fun-lens-indep:*

fun-lens x \bowtie *fun-lens y* \longleftrightarrow $x \neq y$

proof –

obtain $u v :: 'a::two$ **where** $u \neq v$

using *two-diff* **by** *auto*

thus *?thesis*

by (*auto simp add: fun-lens-def lens-indep-def*)

qed

9.2 Function Range Lens

The function range lens allows us to focus on a particular region of a function's range.

definition $fun\text{-}ran\text{-}lens :: ('c \implies 'b) \Rightarrow (('a \Rightarrow 'b) \implies 'a) \Rightarrow (('a \Rightarrow 'c) \implies 'a)$ **where**
 $[lens\text{-}defs]: fun\text{-}ran\text{-}lens\ X\ Y = (\mid lens\text{-}get = \lambda s. get_X \circ get_Y\ s$
 $, lens\text{-}put = \lambda s\ v. put_Y\ s\ (\lambda x::'a. put_X\ (get_Y\ s\ x)\ (v\ x)) \mid)$

lemma $fun\text{-}ran\text{-}mwb\text{-}lens: \llbracket mwb\text{-}lens\ X; mwb\text{-}lens\ Y \rrbracket \implies mwb\text{-}lens\ (fun\text{-}ran\text{-}lens\ X\ Y)$
by $(unfold\text{-}locales, auto\ simp\ add: fun\text{-}ran\text{-}lens\text{-}def)$

lemma $fun\text{-}ran\text{-}wb\text{-}lens: \llbracket wb\text{-}lens\ X; wb\text{-}lens\ Y \rrbracket \implies wb\text{-}lens\ (fun\text{-}ran\text{-}lens\ X\ Y)$
by $(unfold\text{-}locales, auto\ simp\ add: fun\text{-}ran\text{-}lens\text{-}def)$

lemma $fun\text{-}ran\text{-}vwb\text{-}lens: \llbracket vwb\text{-}lens\ X; vwb\text{-}lens\ Y \rrbracket \implies vwb\text{-}lens\ (fun\text{-}ran\text{-}lens\ X\ Y)$
by $(unfold\text{-}locales, auto\ simp\ add: fun\text{-}ran\text{-}lens\text{-}def)$

9.3 Map Lens

The map lens allows us to focus on a particular region of a partial function's range. It is only a mainly well-behaved lens because it does not satisfy the PutGet law when the view is not in the domain.

definition $map\text{-}lens :: 'a \Rightarrow ('b \implies ('a \rightarrow 'b))$ **where**
 $[lens\text{-}defs]: map\text{-}lens\ x = (\mid lens\text{-}get = (\lambda f. the\ (f\ x)), lens\text{-}put = (\lambda f\ u. f(x \mapsto u)) \mid)$

lemma $map\text{-}mwb\text{-}lens: mwb\text{-}lens\ (map\text{-}lens\ x)$
by $(unfold\text{-}locales, simp\text{-}all\ add: map\text{-}lens\text{-}def)$

lemma $source\text{-}map\text{-}lens: \mathcal{S}_{map\text{-}lens\ x} = \{f. x \in dom(f)\}$
by $(force\ simp\ add: map\text{-}lens\text{-}def\ lens\text{-}source\text{-}def)$

lemma $pget\text{-}map\text{-}lens: pget_{map\text{-}lens\ k}\ f = f\ k$
by $(auto\ simp\ add: lens\text{-}partial\text{-}get\text{-}def\ source\text{-}map\text{-}lens)$
 $(auto\ simp\ add: map\text{-}lens\text{-}def, metis\ not\text{-}Some\text{-}eq)$

9.4 List Lens

The list lens allows us to view a particular element of a list. In order to show it is mainly well-behaved we need to define to additional list functions. The following function adds a number undefined elements to the end of a list.

definition $list\text{-}pad\text{-}out :: 'a\ list \Rightarrow nat \Rightarrow 'a\ list$ **where**
 $list\text{-}pad\text{-}out\ xs\ k = xs @ replicate\ (k + 1 - length\ xs)\ undefined$

The following function is like $list\text{-}update$ but it adds additional elements to the list if the list isn't long enough first.

definition $list\text{-}augment :: 'a\ list \Rightarrow nat \Rightarrow 'a \Rightarrow 'a\ list$ **where**
 $list\text{-}augment\ xs\ k\ v = (list\text{-}pad\text{-}out\ xs\ k)[k := v]$

The following function is like (!) but it expressly returns $undefined$ when the list isn't long enough.

definition $nth' :: 'a\ list \Rightarrow nat \Rightarrow 'a$ **where**
 $nth'\ xs\ i = (if\ (length\ xs > i)\ then\ xs\ !\ i\ else\ undefined)$

We can prove some additional laws about list update and append.

lemma *list-update-append-lemma1*: $i < \text{length } xs \implies xs[i := v] @ ys = (xs @ ys)[i := v]$
by (*simp add: list-update-append*)

lemma *list-update-append-lemma2*: $i < \text{length } ys \implies xs @ ys[i := v] = (xs @ ys)[i + \text{length } xs := v]$
by (*simp add: list-update-append*)

We can also prove some laws about our new operators.

lemma *nth'-0* [*simp*]: $\text{nth}'(x \# xs) 0 = x$
by (*simp add: nth'-def*)

lemma *nth'-Suc* [*simp*]: $\text{nth}'(x \# xs) (\text{Suc } n) = \text{nth}' xs n$
by (*simp add: nth'-def*)

lemma *list-augment-0* [*simp*]:
 $\text{list-augment}(x \# xs) 0 y = y \# xs$
by (*simp add: list-augment-def list-pad-out-def*)

lemma *list-augment-Suc* [*simp*]:
 $\text{list-augment}(x \# xs) (\text{Suc } n) y = x \# \text{list-augment } xs n y$
by (*simp add: list-augment-def list-pad-out-def*)

lemma *list-augment-twice*:
 $\text{list-augment}(\text{list-augment } xs i u) j v = (\text{list-pad-out } xs (\text{max } i j))[i:=u, j:=v]$
apply (*auto simp add: list-augment-def list-pad-out-def list-update-append-lemma1 replicate-add[THEN sym] max-def*)
apply (*metis Suc-le-mono add.commute diff-diff-add diff-le-mono le-add-diff-inverse2*)
done

lemma *list-augment-last* [*simp*]:
 $\text{list-augment}(xs @ [y]) (\text{length } xs) z = xs @ [z]$
by (*induct xs, simp-all*)

lemma *list-augment-idem* [*simp*]:
 $i < \text{length } xs \implies \text{list-augment } xs i (xs ! i) = xs$
by (*simp add: list-augment-def list-pad-out-def*)

We can now prove that *list-augment* is commutative for different (arbitrary) indices.

lemma *list-augment-commute*:
 $i \neq j \implies \text{list-augment}(\text{list-augment } \sigma j v) i u = \text{list-augment}(\text{list-augment } \sigma i u) j v$
by (*simp add: list-augment-twice list-update-swap max.commute*)

We can also prove that we can always retrieve an element we have added to the list, since *list-augment* extends the list when necessary. This isn't true of *list-update*.

lemma *nth-list-augment*: $\text{list-augment } xs k v ! k = v$
by (*simp add: list-augment-def list-pad-out-def*)

lemma *nth'-list-augment*: $\text{nth}'(\text{list-augment } xs k v) k = v$
by (*auto simp add: nth'-def nth-list-augment list-augment-def list-pad-out-def*)

The length is expanded if not already long enough, or otherwise left as it is.

lemma *length-list-augment-1*: $k \geq \text{length } xs \implies \text{length}(\text{list-augment } xs k v) = \text{Suc } k$
by (*simp add: list-augment-def list-pad-out-def*)

lemma *length-list-augment-2*: $k < \text{length } xs \implies \text{length}(\text{list-augment } xs k v) = \text{length } xs$
by (*simp add: list-augment-def list-pad-out-def*)

```

  apply (metis (full-types) hd-conv-nth hd-def length-greater-0-conv list.case(1) nth'-def)

9.6 Record Field Lenses

We also add support for record lenses. Every record created can yield a lens for each field. These cannot be created generically and thus must be defined case by case as new records are created. We thus create a new Isabelle outer syntax command **alphabet** which enables this. We first create syntax that allows us to obtain a lens from a given field using the internal record syntax translations.

```

abbreviation (input) fld-put f ≡ (λ σ u. f (λ-. u) σ)

```

```

syntax

```

```

  -FLDLENS :: id ⇒ logic (⟨FLDLENS →⟩)

```

```

translations

```

$FOLDLENS\ x \Rightarrow \langle \text{lens-get} = x, \text{lens-put} = \text{CONST fld-put } (-\text{update-name } x) \rangle$

We also allow the extraction of the "base lens", which characterises all the fields added by a record without the extension.

syntax

$-BASELENS :: id \Rightarrow logic \langle \text{BASELENS } - \rangle$

abbreviation $(input)\ base\text{-lens } t\ e\ m \equiv \langle \text{lens-get} = t, \text{lens-put} = \lambda s\ v.\ e\ v\ (m\ s) \rangle$

ML \langle

```

fun baselens-tr [Free (name, -)] =
  let
    val extend = Free (name ^ .extend, dummyT);
    val truncate = Free (name ^ .truncate, dummyT);
    val more = Free (name ^ .more, dummyT);
  in
    Const (@{const-syntax base-lens}, dummyT) $ truncate $ extend $ more
  end
| baselens-tr - = raise Match;

```

parse-translation $\langle [(@\{\text{syntax-const } -BASELENS\}, K\ baselens\text{-tr})] \rangle$

We also introduce the **alphabet** command that creates a record with lenses for each field. For each field a lens is created together with a proof that it is very well-behaved, and for each pair of lenses an independence theorem is generated. Alphabets can also be extended which yields sublens proofs between the extension field lens and record extension lenses.

named-theorems *lens*

ML-file $\langle \text{Lens-Lib.ML} \rangle$

ML-file $\langle \text{Lens-Record.ML} \rangle$

The following theorem attribute stores splitting theorems for alphabet types which which is useful for proof automation.

named-theorems *alpha-splits*

We supply a helpful tactic to remove the subscripted v characters from subgoals. These exist because the internal names of record fields have them.

method *rename-alpha-vars* = tactic $\langle \text{Lens-Utils.rename-alpha-vars} \rangle$

9.7 Locale State Spaces

Alternative to the alphabet command, we also introduce the statespace command, which implements Schirmer and Wenzel's locale-based approach to state space modelling [9].

It has the advantage of allowing multiple inheritance of state spaces, and also variable names are fully internalised with the locales. The approach is also far simpler than record-based state spaces.

It has the disadvantage that variables may not be fully polymorphic, unlike for the alphabet command. This makes it in general unsuitable for UTP theory alphabets.

ML-file $\langle \text{Lens-Statespace.ML} \rangle$

9.8 Type Definition Lens

Every type defined by a **typedef** command induces a partial bijective lens constructed using the abstraction and representation functions.

```
context type-definition
begin
```

```
definition typedef-lens :: 'b  $\Rightarrow$  'a ( $\langle$ typedefL $\rangle$ ) where
[lens-defs]: typedefL = ( $\langle$  lens-get = Abs, lens-put = ( $\lambda$  s. Rep)  $\rangle$ )
```

```
lemma pbij-typedef-lens [simp]: pbij-lens typedefL
by (unfold-locales, simp-all add: lens-defs Rep-inverse)
```

```
lemma source-typedef-lens:  $\mathcal{S}_{typedef\ L} = A$ 
using Rep-cases by (auto simp add: lens-source-def lens-defs Rep)
```

```
lemma bij-typedef-lens-UNIV:  $A = UNIV \Rightarrow$  bij-lens typedefL
by (auto intro: pbij-vwb-is-bij-lens simp add: mwb-UNIV-src-is-vwb-lens source-typedef-lens)
```

```
end
```

9.9 Mapper Lenses

```
definition lmap-lens ::
(( $\alpha \Rightarrow \beta$ )  $\Rightarrow$  ( $\gamma \Rightarrow \delta$ ))  $\Rightarrow$ 
(( $\beta \Rightarrow \alpha$ )  $\Rightarrow$  ( $\delta \Rightarrow \gamma$ )  $\Rightarrow$ 
( $\gamma \Rightarrow \alpha$ )  $\Rightarrow$ 
( $\beta \Rightarrow \alpha$ )  $\Rightarrow$ 
( $\delta \Rightarrow \gamma$ ) where
[lens-defs]:
lmap-lens f g h l = ( $\langle$ 
lens-get = f (getl),
lens-put = g o (putl) o h  $\rangle$ )
```

The parse translation below yields a heterogeneous mapping lens for any record type. This is achieved through the utility function above that constructs a functorial lens. This takes as input a heterogeneous mapping function that lifts a function on a record's extension type to an update on the entire record, and also the record's "more" function. The first input is given twice as it has different polymorphic types, being effectively a type functor construction which are not explicitly supported by HOL. We note that the *more-update* function does something similar to the extension lifting, but is not precisely suitable here since it only considers homogeneous functions, namely of type $'a \Rightarrow 'a$ rather than $'a \Rightarrow 'b$.

```
syntax
-lmap :: id  $\Rightarrow$  logic ( $\langle$ lmap[-] $\rangle$ )
```

```
ML  $\langle$ 
fun lmap-tr [Free (name, -)] =
let
val extend = Free (name ^ .extend, dummyT);
val truncate = Free (name ^ .truncate, dummyT);
val more = Free (name ^ .more, dummyT);
val map-ext = Abs (f, dummyT,
Abs (r, dummyT,
extend $ (truncate $ Bound 0) $ (Bound 1 $ (more $ (Bound 0))))))
```

```

    in
      Const (@{const-syntax lmap-lens}, dummyT) $ map-ext $ map-ext $ more
    end
  | lmap-tr - = raise Match;
}

```

parse-translation $\langle [(@\{syntax-const -lmap\}, K\ lmap-tr)] \rangle$
