

Probabilistic Primality Testing

Daniel Stüwe and Manuel Eberl

February 23, 2021

Abstract

The most efficient known primality tests are *probabilistic* in the sense that they use randomness and may, with some probability, mistakenly classify a composite number as prime – but never a prime number as composite. Examples of this are the Miller–Rabin test, the Solovay–Strassen test, and (in most cases) Fermat’s test.

This entry defines these three tests and proves their correctness. It also develops some of the number-theoretic foundations, such as Carmichael numbers and the Jacobi symbol with an efficient executable algorithm to compute it.

3 The Jacobi Symbol

theory *Jacobi-Symbol*
imports
 Legendre-Symbol
 Algebraic-Auxiliaries
begin

The Jacobi symbol is a generalisation of the Legendre symbol to non-primes [?, ?]. It is defined as

$$\left(\frac{a}{n}\right) = \left(\frac{a}{p_1}\right)^{k_1} \cdots \left(\frac{a}{p_l}\right)^{k_l}$$

where $\left(\frac{a}{p}\right)$ denotes the Legendre symbol, a is an integer, n is an odd natural number and $p_1^{k_1} \dots p_l^{k_l}$ is its prime factorisation.

There is, however, a fairly natural generalisation to all non-zero integers for n . It is less clear what a good choice for $n = 0$ is; Mathematica and Maxima adopt the convention that $\left(\frac{\pm 1}{0}\right) = 1$ and $\left(\frac{a}{0}\right) = 0$ otherwise. However, we chose the slightly different convention $\left(\frac{a}{0}\right) = 0$ for *all* a because then the Jacobi symbol is completely multiplicative in both arguments without any restrictions.

definition *Jacobi* $:: \text{int} \Rightarrow \text{int} \Rightarrow \text{int}$ **where**

True

<proof>

lemma *eq-bernoulli-pmfI*:

assumes pmf p *True* = x

shows p = bernoulli-pmf x

<proof>

We require a probabilistic primality test to never classify a prime as composite. It may, however, mistakenly classify composites as primes.

locale *prob-primality-test* =

fixes P :: nat \Rightarrow nat \Rightarrow bool **and** n :: nat

assumes P-works: odd n \Longrightarrow 2 \leq a \Longrightarrow a < n \Longrightarrow prime n \Longrightarrow P n a

begin

lemma *FalseD*:

assumes false: False \in set-pmf (*primality-test* P n)

shows \neg prime n

<proof>

theorem *prime*:

assumes odd-prime: prime n

shows *primality-test* P n = return-pmf *True*

<proof>

end

We call a primality test *q-good* for a fixed positive real number *q* if the probability that it mistakenly classifies a composite as a prime is less than *q*.

locale *good-prob-primality-test* = *prob-primality-test* +

fixes q :: real

assumes q-pos: q > 0

assumes composite-witness-bound:

\neg prime n \Longrightarrow 2 < n \Longrightarrow odd n \Longrightarrow

```

    real (card {a . 2 ≤ a ∧ a < n ∧ P n a}) < q * real (n - 2)
begin

lemma composite-aux:
  assumes ¬prime n
  shows measure-pmf.expectation (primality-test P n) of-bool < q
  ⟨proof⟩

theorem composite:
  assumes ¬prime n
  shows pmf (primality-test P n) True < q
  ⟨proof⟩

end

10 Fermat's Test

```

theory Fermat-Test
imports
  Fermat-Witness
  Generalized-Primality-Test
begin

definition fermat-test = primality-test (λn a. fermat-liar a n)

The Fermat test is a good probabilistic primality test on non-Carmichael
numbers.

locale fermat-test-not-Carmichael-number =
  fixes n :: nat
  assumes not-Carmichael-number: ¬Carmichael-number n ∨ n < 3
begin

sublocale fermat-test: good-prob-primality-test λa n. fermat-liar n a n 1 / 2
  rewrites primality-test (λ a n. fermat-liar n a) = fermat-test
  ⟨proof⟩

end

lemma not-coprime-imp-fermat-witness:
  fixes n :: nat
  assumes n > 1 ¬coprime a n
  shows fermat-witness a n
  ⟨proof⟩

theorem fermat-test-prime:
  assumes prime n
  shows fermat-test n = return-pmf True

```

<proof>

theorem *fermat-test-composite:*

assumes $\neg \text{prime } n \ \neg \text{Carmichael-number } n \ \vee \ n < 3$

shows $\text{pmf } (\text{fermat-test } n) \ \text{True} < 1 / 2$

<proof>

For a Carmichael number n , Fermat's test as defined above mistakenly returns 'True' with probability $(\varphi(n) - 1)/(n - 2)$. This probability is close to 1 if n has few and big prime factors; it is not quite as bad if it has many and/or small factors, but in that case, simple trial division can also detect compositeness.

Moreover, Fermat's test only succeeds for a Carmichael number if it happens to guess a number that is not coprime to n . In that case, the fact that we have found a number between 2 and n that is not coprime to n alone is proof that n is composite, and indeed we can even find a non-trivial factor by computing the GCD. This means that for Carmichael numbers, Fermat's test is essentially no better than the very crude method of attempting to guess numbers coprime to n .

This means that, in general, Fermat's test is not very helpful for Carmichael numbers.

theorem *fermat-test-Carmichael-number:*

assumes *Carmichael-number* n

shows $\text{fermat-test } n = \text{bernoulli-pmf } (\text{real } (\text{totient } n - 1) / \text{real } (n - 2))$

<proof>

end

11 The Miller–Rabin Test

theory *Miller-Rabin-Test*

imports

Fermat-Witness

Generalized-Primality-Test

begin

definition $\text{miller-rabin} = \text{primality-test } (\lambda n \ a. \ \text{strong-fermat-liar } a \ n)$

The test is actually $\frac{1}{4}$ good, but we only show $\frac{1}{2}$, since the former is much more involved.

interpretation *miller-rabin: good-prob-primality-test* $\lambda n \ a. \ \text{strong-fermat-liar } a \ n$
 $n \ 1 / 2$

rewrites $\text{primality-test } (\lambda n \ a. \ \text{strong-fermat-liar } a \ n) = \text{miller-rabin}$

<proof>

end
