Transitive closure according to Roy-Floyd-Warshall

Makarius Wenzel

December 17, 2016

Abstract

This formulation of the Roy-Floyd-Warshall algorithm for the transitive closure bypasses matrices and arrays, but uses a more direct mathematical model with adjacency functions for immediate predecessors and successors. This can be implemented efficiently in functional programming languages and is particularly adequate for sparse relations.

Contents

1 Transitive closure algorithm

The Roy-Floyd-Warshall algorithm takes a finite relation as input and produces its transitive closure as output. It iterates over all elements of the field of the relation and maintains a cumulative approximation of the result: step 0 starts with the original relation, and step *Suc n* connects all paths over the intermediate element *n*. The final approximation coincides with the full transitive closure.

This algorithm is often named after "Floyd", "Warshall", or "Floyd-Warshall", but the earliest known description is due to B. Roy [1].

Subsequently we use a direct mathematical model of the relation, bypassing matrices and arrays that are usually seen in the literature. This is more efficient for sparse relations: only the adjacency for immediate predecessors and successors needs to be maintained, not the square of all possible

combinations. Moreover we do not have to worry about mutable data structures in a multi-threaded environment. See also the graph implementation in the Isabelle sources `$ISABELLE_HOME/src/Pure/General/graph.ML` and `$ISABELLE_HOME/src/Pure/General/graph.scala`.

type-synonym *relation* = (*nat* × *nat*) *set*

fun *steps* :: *relation* ⇒ *nat* ⇒ *relation*
where
  steps rel 0 = *rel*
| *steps rel* (*Suc n*) =
    steps rel n ∪ {(*x*, *y*). (*x*, *n*) ∈ *steps rel n* ∧ (*n*, *y*) ∈ *steps rel n*}

Implementation view on the relation:

definition *preds* :: *relation* ⇒ *nat* ⇒ *nat set*
  where *preds rel y* = {*x*. (*x*, *y*) ∈ *rel*}

definition *succs* :: *relation* ⇒ *nat* ⇒ *nat set*
  where *succs rel x* = {*y*. (*x*, *y*) ∈ *rel*}

lemma
  steps rel (*Suc n*) =
    steps rel n ∪ {(*x*, *y*). *x* ∈ *preds* (*steps rel n*) *n* ∧ *y* ∈ *succs* (*steps rel n*) *n*}
  by (*simp add*: *preds-def succs-def*)

The main function requires an upper bound for the iteration, which is left unspecified here (via Hilbert's choice).

definition *is-bound* :: *relation* ⇒ *nat* ⇒ *bool*
  where *is-bound rel n* ⟷ (∀ *m* ∈ *Field rel*. *m* < *n*)

definition *transitive-closure rel* = *steps rel* (*SOME n*. *is-bound rel n*)

2 Correctness proof

2.1 Miscellaneous lemmas

lemma steps-rel: (x, y) ∈ rel ⟹ (x, y) ∈ steps rel n
  by (induct n) auto
```

2.2 Bounded closure

The bounded closure connects all transitive paths over elements below a given bound. For an upper bound of the relation, this coincides with the full transitive closure.

```
inductive-set Clos :: relation ⇒ nat ⇒ relation
  for rel :: relation and n :: nat
where
  base: (x, y) ∈ Clos rel n if (x, y) ∈ rel
| step: (x, y) ∈ Clos rel n if (x, z) ∈ Clos rel n and (z, y) ∈ Clos rel n and z <
n

theorem Clos-closure:
  assumes is-bound rel n
  shows (x, y) ∈ Clos rel n ⟷ (x, y) ∈ rel⁺
proof
  show (x, y) ∈ rel⁺ if (x, y) ∈ Clos rel n
    using that by induct simp-all
  show (x, y) ∈ Clos rel n if (x, y) ∈ rel⁺
    using that

2.3 Main theorem

The main theorem follows immediately from the key observations above. Note that the assumption of finiteness gives a bound for the iteration, although the details are left unspecified. A concrete implementation could choose the the maximum element + 1, or iterate directly over the data structures for the *preds* and *succs* implementation.

theorem *transitive-closure-correctness*:
  assumes *finite rel*
  shows *transitive-closure rel* = rel^+
proof −

  have $(x, y) \in$ *steps rel ?N* $\longleftrightarrow$ $(x, y) \in rel^+$ **for** *x y*
  proof −
    have $(x, y) \in$ *steps rel ?N* $\longleftrightarrow$ $(x, y) \in$ *Clos rel ?N*
      by (*rule steps-Clos-equiv*)
    also have ... $\longleftrightarrow$ $(x, y) \in rel^+$
      using *is-bound* **by** (*rule Clos-closure*)
    finally show *?thesis* **.**
  qed
  then show *?thesis* **unfolding** *transitive-closure-def* **by** *auto*
qed

3 Alternative formulation

The core of the algorithm may be expressed more declaratively as follows, using an inductive definition to imitate a logic-program. This is equivalent to the function specification *steps* from above.

inductive *Steps* :: *relation* ⇒ *nat* ⇒ *nat* × *nat* ⇒ *bool*
  for *rel* :: *relation*
where
  base: *Steps rel* 0 (x, y) **if** $(x, y) \in$ *rel*
| *copy*: *Steps rel* (*Suc n*) (x, y) **if** *Steps rel n* (x, y)
| *step*: *Steps rel* (*Suc n*) (x, y) **if** *Steps rel n* (x, n) **and** *Steps rel n* (n, y)

lemma *steps-equiv*: $(x, y) \in$ *steps rel n* $\longleftrightarrow$ *Steps rel n* (x, y)
proof
  show *Steps rel n* (x, y) **if** $(x, y) \in$ *steps rel n*
    using *that*
  proof (*induct n arbitrary*: *x y*)
    case 0
    then have $(x, y) \in$ *rel* **by** *simp*

```
    then show ?case by (rule base)
  next
    case (Suc n)
    from Suc(2) show ?case
    proof (cases rule: steps-cases)
      case copy
      with Suc(1) have Steps rel n (x, y) .
      then show ?thesis by (rule Steps.copy)
    next
      case step
      with Suc(1) have Steps rel n (x, n) and Steps rel n (n, y)
        by simp-all
      then show ?thesis by (rule Steps.step)
    qed
  qed
  show (x, y) ∈ steps rel n if Steps rel n (x, y)
    using that by induct simp-all
qed
```
