Stone-Kleene Relation Algebras

Walter Guttmann

March 17, 2025

Abstract

We develop Stone-Kleene relation algebras, which expand Stone relation algebras with a Kleene star operation to describe reachability in weighted graphs. Many properties of the Kleene star arise as a special case of a more general theory of iteration based on Conway semirings extended by simulation axioms. This includes several theorems representing complex program transformations. We formally prove the correctness of Conway's automata-based construction of the Kleene star of a matrix. We prove numerous results useful for reasoning about weighted graphs.

1 Synopsis and Motivation

This document describes the following five theory files:

- * Iterings describes a general iteration operation that works for many different computation models. We first consider equational axioms based on variants of Conway semirings. We expand these structures by generalised simulation axioms, which hold in total and general correctness models, not just in partial correctness models like the induction axioms. Simulation axioms are still powerful enough to prove separation theorems and Back's atomicity refinement theorem [4].
- * Kleene Algebras form a particular instance of iterings in which the iteration is implemented as a least fixpoint. We implement them based on Kozen's axioms [13], but most results are inherited from Conway semirings and iterings.
- * Kleene Relation Algebras introduces Stone-Kleene relation algebras, which combine Stone relation algebras and Kleene algebras. This is similar to relation algebras with transitive closure [16] but allows us to talk about reachability in weighted graphs. Many results in this theory are useful for verifying the correctness of Prim's and Kruskal's minimum spanning tree algorithms.
- * Subalgebras of Kleene Relation Algebras studies the regular elements of a Stone-Kleene relation algebra and shows that they form a Kleene relation subalgebra.
- * Matrix Kleene Algebras lifts the Kleene star to finite square matrices using Conway's automata-based construction. This involves an operation to restrict matrices to specific indices and a calculus for such restrictions. An implementation for the Kleene star of matrices was given in [3] without proof; this is the first formally verified correctness proof.

The development is based on a theory of Stone relation algebras [11, 12]. We apply Stone-Kleene relation algebras to verify Prim's minimum spanning tree algorithm in Isabelle/HOL in [10].

Related libraries for Kleene algebras, regular algebras and relation algebras in the Archive of Formal Proofs are [1, 2, 8]. Kleene algebras are covered in the theory Kleene_Algebra/Kleene_Algebra.thy, but unlike

the present development it is not based on general algebras using simulation axioms, which are useful to describe various computation models. The theory Regular_Algebras/Regular_Algebras.thy compares different axiomatisations of regular algebras. The theory Kleene_Algebra/Matrix.thy covers matrices over dioids, but does not implement the Kleene star of matrices. The theory Relation_Algebra/Relation_Algebra_RTC.thy combines Kleene algebras and relation algebras, but is very limited in scope and not applicable as we need the weaker axioms of Stone relation algebras.

2 Iterings

This theory introduces algebraic structures with an operation that describes iteration in various relational computation models. An iteration describes the repeated sequential execution of a computation. This is typically modelled by fixpoints, but different computation models use different fixpoints in the refinement order. We therefore look at equational and simulation axioms rather than induction axioms. Our development is based on [9] and the proposed algebras generalise Kleene algebras.

We first consider a variant of Conway semirings [5] based on idempotent left semirings. Conway semirings expand semirings by an iteration operation satisfying Conway's sumstar and productstar axioms [7]. Many properties of iteration follow already from these equational axioms.

Next we introduce iterings, which use generalised versions of simulation axioms in addition to sumstar and productstar. Unlike the induction axioms of the Kleene star, which hold only in partial-correctness models, the simulation axioms are also valid in total and general correctness models. They are still powerful enough to prove the correctness of complex results such as separation theorems of [6] and Back's atomicity refinement theorem [4, 17].

begin

2.1 Conway Semirings

In this section, we consider equational axioms for iteration. The algebraic structures are based on idempotent left semirings, which are expanded by a unary iteration operation. We start with an unfold property, one inequality of the sliding rule and distributivity over joins, which is similar to Conway's sumstar.

```
class circ = fixes circ :: 'a \Rightarrow 'a \ ( \leftarrow ) [100] \ 100 )
```

```
class left-conway-semiring = idempotent-left-semiring + circ + assumes circ-left-unfold: 1 \sqcup x * x^{\circ} = x^{\circ} assumes circ-left-slide: (x * y)^{\circ} * x \leq x * (y * x)^{\circ} assumes circ-sup-1: (x \sqcup y)^{\circ} = x^{\circ} * (y * x^{\circ})^{\circ} begin

We obtain one inequality of Conway's productstar, as well as of the other unfold rule.

3 Kleene Algebras

Kleene algebras have been axiomatised by Kozen to describe the equational theory of regular languages [13]. Binary relations are another important model. This theory implements variants of Kleene algebras based on idempotent left semirings [15]. The weakening of some semiring axioms allows the treatment of further computation models. The presented algebras are special cases of iterings, so many results can be inherited.

theory Kleene-Algebras

imports Iterings

begin

We start with left Kleene algebras, which use the left unfold and left induction axioms of Kleene algebras.

```
class star =
fixes star :: 'a \Rightarrow 'a \ (\langle -^* \rangle \ [100] \ 100)
class left-kleene-algebra = idempotent-left-semiring + star +

A Kleene algebra is obtained by requiring an idempotent semiring.

 $class\ kleene-algebra = left-zero-kleene-algebra + idempotent-semiring$

The following classes are variants of Kleene algebras expanded by an additional iteration operation. This is useful to study the Kleene star in computation models that do not use least fixpoints in the refinement order as the semantics of recursion.

 ${\bf class}\ {\it left-kleene-conway-semiring} = {\it left-kleene-algebra} + {\it left-conway-semiring} \\ {\bf begin}$

lemma star-below-circ:

4 Kleene Relation Algebras

This theory combines Kleene algebras with Stone relation algebras. Relation algebras with transitive closure have been studied by [16]. The weakening to Stone relation algebras allows us to talk about reachability in weighted graphs, for example.

Many results in this theory are used in the correctness proof of Prim's minimum spanning tree algorithm. In particular, they are concerned with the exchange property, preservation of parts of the invariant and with establishing parts of the postcondition.

 ${\bf theory}\ {\it Kleene-Relation-Algebras}$

end

 ${\bf imports}\ Stone-Relation-Algebras. Relation-Algebras\ Kleene-Algebras$

begin

We first note that bounded distributive lattices can be expanded to Kleene algebras by reusing some of the operations.

```
{f sublocale}\ bounded\mbox{-}distrib\mbox{-}lattice < comp\mbox{-}inf:\ bounded\mbox{-}kleene\mbox{-}algebra\ {f where}\ star
=\lambda x. top and one = top and times = inf

 apply simp
 by (simp add: inf-assoc)
```

We add the Kleene star operation to each of bounded distributive allegories, pseudocomplemented distributive allegories and Stone relation algebras. We start with single-object bounded distributive allegories.

4.1 Prim's Algorithm

The following results are used for proving the correctness of Prim's minimum spanning tree algorithm.

4.1.1 Preservation of Invariant

We first treat the preservation of the invariant. The following lemma shows that the while-loop preserves that v represents the nodes of the constructed tree. The remaining lemmas in this section show that t is a spanning tree. The exchange property is treated in the following two sections.

```
{\bf lemma}\ reachable\hbox{-}inv\hbox{:}
```

```
assumes vector\ v and e \le v * - v^T and e * t = bot and v^T = r^T * t^* shows (v \sqcup e^T * top)^T = r^T * (t \sqcup e)^* proof — have 1: v^T \le r^T * (t \sqcup e)^* by (simp\ add:\ assms(4)\ mult-right-isotone\ star.circ-sub-dist) have 2: (e^T * top)^T = top * e by (simp\ add:\ conv-dist-comp) also have ... = top * (v * - v^T \sqcap e) by (simp\ add:\ assms(2)\ inf-absorb2) also have ... \le top * (v * top \sqcap e) using inf.sup-left-isotone\ mult-right-isotone\ top-greatest by blast also have ... = top * v^T * e

4.1.2 Exchange gives Spanning Trees

The following abbreviations are used in the spanning tree application using Prim's algorithm to construct the new tree for the exchange property. It is obtained by replacing an edge with one that has minimal weight and reversing the path connecting these edges. Here, w represents a weighted graph, v represents a set of nodes and e represents an edge.

```
abbreviation prim-E :: 'a \Rightarrow 'a \Rightarrow 'a \Rightarrow 'a \text{ where } prim-E \ w \ v \ e \equiv w \ \sqcap --v \ * -v^T \ \sqcap \ top \ * \ e \ * \ w^T \ * abbreviation prim-P :: 'a \Rightarrow 'a \Rightarrow 'a \Rightarrow 'a \text{ where } prim-P \ w \ v \ e \equiv w \ \sqcap -v \ * -v^T \ \sqcap \ top \ * \ e \ * \ w^T \ * abbreviation prim-EP :: 'a \Rightarrow 'a \Rightarrow 'a \Rightarrow 'a \text{ where } prim-EP \ w \ v \ e \equiv w \ \sqcap -v^T \ \sqcap \ top \ * \ e \ * \ w^T \ * abbreviation prim-W :: 'a \Rightarrow 'a \Rightarrow 'a \text{ where } prim-W \ w \ v \ e \equiv (w \ \sqcap -(prim-EP \ w \ v \ e)) \ \sqcup \ (prim-P \ w \ v \ e)^T \ \sqcup \ e
```

The lemmas in this section are used to show that the relation after exchange represents a spanning tree. The results in the next section are used to show that it is a minimum spanning tree.

Some of the following lemmas already hold in pseudocomplemented distributive Kleene allegories.

4.1.3 Exchange gives Minimum Spanning Trees

The lemmas in this section are used to show that the after exchange we obtain a minimum spanning tree. The following lemmas show various interactions between the three constituents of the tree after exchange.

```

4.2.3 Exchange gives Minimum Spanning Trees

The lemmas in this section are used to show that the after exchange we obtain a minimum spanning tree. The following lemmas show that the relation characterising the edge across the cut is an arc.

```
lemma kruskal-edge-arc:
   assumes equivalence F
   and forest w
   and arc e
   and regular F
   and F \leq forest\text{-}components \ (F \sqcap w)
   and regular w
   and w*e^T = bot
   and e*F*e = bot
   and e^T \leq w^*
   shows arc \ (w \sqcap top*e^T*w^{T*} \sqcap F*e^T*top \sqcap top*e*-F)

proof (unfold \ arc\text{-}expanded, intro \ conjI)

let ?E = top*e^T*w^{T*}
```

6 Matrix Kleene Algebras

This theory gives a matrix model of Stone-Kleene relation algebras. The main result is that matrices over Kleene algebras form Kleene algebras. The automata-based construction is due to Conway [7]. An implementation of the construction in Isabelle/HOL that extends [2] was given in [3] without a correctness proof.

For specifying the size of matrices, Isabelle/HOL's type system requires the use of types, not sets. This creates two issues when trying to implement Conway's recursive construction directly. First, the matrix size changes for recursive calls, which requires dependent types. Second, some submatrices used in the construction are not square, which requires typed Kleene algebras [14], that is, categories of Kleene algebras.

Because these instruments are not available in Isabelle/HOL, we use square matrices with a constant size given by the argument of the Kleene star operation. Smaller, possibly rectangular submatrices are identified by two lists of indices: one for the rows to include and one for the columns to include. Lists are used to make recursive calls deterministic; otherwise sets would be sufficient.

6.1 Matrix Restrictions

In this section we develop a calculus of matrix restrictions. The restriction of a matrix to specific row and column indices is implemented by the following function, which keeps the size of the matrix and sets all unused entries to bot.

```
definition restrict-matrix :: 'a list \Rightarrow ('a,'b::bot) square \Rightarrow 'a list \Rightarrow ('a,'b) square (\langle - \langle - \rangle \rightarrow [90,41,90] \ 91) where restrict-matrix as f bs = (\lambda(i,j) . if List.member as i \land List.member bs j then f (i,j) else bot)
```

The following function captures Conway's automata-based construction of the Kleene star of a matrix. An index k is chosen and s contains all other indices. The matrix is split into four submatrices a, b, c, d including/not including row/column k. Four matrices are computed containing the entries given by Conway's construction. These four matrices are added to obtain the result. All matrices involved in the function have the same size, but matrix restriction is used to set irrelevant entries to bot.

```
primrec star-matrix':: 'a\ list \Rightarrow ('a,'b::\{star,times,bounded-semilattice-sup-bot\}) square \Rightarrow ('a,'b)\ square\ \mathbf{where}
```

```
star-matrix' \ Nil \ g = mbot \ |
star-matrix' \ (k\#s) \ g = (
let \ r = [k] \ in
let \ a = r\langle g \rangle r \ in
let \ b = r\langle g \rangle s \ in
let \ c = s\langle g \rangle r \ in
let \ d = s\langle g \rangle s \ in
let \ ds = r\langle star \ o \ a \rangle r \ in
let \ ds = star-matrix' \ s \ d \ in
let \ e = a \oplus b \odot ds \odot c \ in
let \ es = r\langle star \ o \ e \rangle r \ in
let \ f = d \oplus c \odot as \odot b \ in
let \ fs = star-matrix' \ s \ f \ in
es \oplus as \odot b \odot fs \oplus ds \odot c \odot es \oplus fs
)
```

The Kleene star of the whole matrix is obtained by taking as indices all elements of the underlying type 'a. This is conveniently supplied by the enum class.

```
fun star-matrix :: ('a::enum,'b::{star,times,bounded-semilattice-sup-bot}) square \Rightarrow ('a,'b) square (\leftarrow0) [100] 100) where star-matrix f = star-matrix' (enum-class.enum::'a list) f
```

The following lemmas deconstruct matrices with non-empty restrictions.

```
lemma restrict-empty-left:
  [\langle f \rangle ls = mbot]

6.2 Matrices form a Kleene Algebra

Matrices over Kleene algebras form a Kleene algebra using Conway's construction. It remains to prove one unfold and two induction axioms of the Kleene star. Each proof is by induction over the size of the matrix represented by an index list.

interpretation matrix-kleene-algebra: kleene-algebra-var where sup = sup-matrix and less-eq = less-eq-matrix and less = less-matrix and bot = bot-matrix::('a::enum,'b::kleene-algebra) square and one = one-matrix and times
