Chapter 1

Overview

pGCL is both a programming language and a specification language that incorporates both probabilistic and nondeterministic choice, in a unified manner. Program verification is by refinement or annotation (or both), using either Hoare triples, or weakest-precondition entailment, in the style of GCL [Dijkstra, 1975].

This document is divided into three parts: Chapter 2 gives a tutorial-style introduction to pGCL, and demonstrates the tools provided by the package; Chapter 3 covers the development of the semantic interpretation: expectation transformers; and Chapter 4 covers the formalisation of the language primitives, the associated healthiness results, and the tools for structured and automated reasoning. This second part follows the technical development of the pGCL theory package, in detail. It is not a great place to start learning pGCL. For that, see either the tutorial or McIver and Morgan [2004].

This formalisation was first presented (as an overview) in Cock [2012]. The language has previously been formalised in HOL4 by Hurd et al. [2005]. Two substantial results using this package were presented in Cock [2013], Cock [2014a] and Cock [2014b].
Chapter 2

Introduction to pGCL

2.1 Language Primitives

theory Primitives imports ../pGCL begin

Programs in pGCL are probabilistic automata. They can do anything a traditional program can, plus, they may make truly probabilistic choices.

2.1.1 The Basics

Imagine flipping a pair of fair coins: \( a \) and \( b \). Using a record type for the state allows a number of syntactic niceties, which we describe shortly:

\[
\text{datatype } \text{coin} = \text{Heads} | \text{Tails}
\]

\[
\text{record } \text{coins} =
\]

\[
\begin{align*}
    a :: & \text{coin} \\
    b :: & \text{coin}
\end{align*}
\]

The primitive state operation is \( \text{Apply} \), which takes a state transformer as an argument, constructs the pGCL equivalent. Thus \( \text{Apply} (a\text{-update} (\lambda s. \text{Heads})) \) sets the value of coin \( a \) to \( \text{Heads} \). As records are so common as state types, we introduce syntax to make these update neater: The same program may be defined more simply as \( \text{Apply} (a\text{-update} (\lambda s. \text{Heads})) \) (note that the syntax translation involved does not apply to Latex output, and thus this lemma appears trivial):

\[
\text{lemma }
\]

\[
\text{Apply} (\lambda s. s \{ a := \text{Heads} \}) = (a := (\lambda s. \text{Heads}))
\]

\[
\langle \text{proof} \rangle
\]

We can treat the record’s fields as the names of \( \text{variables} \). Note that the right-hand side of an assignment is always a function of the current state. Thus we may use a record accessor directly, for example \( \text{Apply} (\lambda s. s \{ a := b \}) \), which updates \( a \) with the current value of \( b \). If we wish to formally...
establish that the previous statement is correct i.e. that in the final state, 
a really will have whatever value b had in the initial state, we must first 
introduce the assertion language.

2.1.2 Assertion and Annotation

Assertions in pGCL are real-valued functions of the state, which are often 
termed expectations, for reasons which shortly be clear. Initially, 
however, we need only consider standard expectations: those derived from 
a binary predicate. A predicate P::’s ⇒ bool is embedded as « P »::’s ⇒ real, such that 
P s −→ « P » s = 1 ∧ ¬ P s −→ « P » s = 0.

An annotation consists of an assertion on the initial state and one on the 
final state, which for standard expectations may be interpreted as ‘if P 
holds in the initial state, then Q will hold in the final state’. These are 
in weakest-precondition form: we assert that the precondition implies the 
weakest precondition: the weakest assertion on the initial state, which implies 
that the postcondition must hold on the final state. So far, this is identical 
to the standard approach. Remember, however, that we are working with 
real-valued assertions. For standard expectations, the logic is nevertheless 
identical, if the implication ∀ s. P s −→ Q s is substituted with the equivalent 
Apply ((∗) 2) ;; Apply (λs. s / s)) «λs. s = 1» is:

lemma
\[ \forall x. «λs. b s = x» ⊢ wp (a := b) «λs. a s = x» \]
⟨proof⟩

Any ordinary computation and its associated annotation can be expressed 
in this form.

2.1.3 Probability

Next, we introduce the syntax x ;; y for the sequential composition of x and 
y, and also demonstrate that one can operate directly on a real-valued (and 
thus infinite) state space:

lemma
«λs::real. s ≠ 0» ⊢ wp (Apply ((*) 2) ;; Apply (λs. s / s)) «λs. s = 1»
⟨proof⟩

So far, we haven’t done anything that required probabilities, or expectations 
other than 0 and 1. As an example of both, we show that a single coin toss is 
fair. We introduce the syntax x_p⊕ y for a probabilistic choice between x and 
y. This program behaves as x with probability p, and as y with probability 
(1::’a) − p. The probability may depend on the state, and is therefore of
2.1. LANGUAGE PRIMITIVES

The following annotation states that the probability of heads is exactly 1/2:

definition
flip-a :: real ⇒ coins prog
where
flip-a p = a := (λ-. Heads) (λs. p)⊕ a := (λ-. Tails)

lemma
(λs. 1/2) = wp (flip-a (1/2)) «λs. a s = Heads»

(proof)

2.1.4 Nondeterminism

We can also under-specify a program, using the nondeterministic choice operator, x △ y. This is interpreted demonically, giving the pointwise minimum of the pre-expectations for x and y: the chance of seeing heads, if your opponent is allowed choose between a pair of coins, one biased 2/3 heads and one 2/3 tails, and then flips it, is at least 1/3, but we can make no stronger statement:

lemma
λs. 1/3 ⊩ wp (flip-a (2/3) △ flip-a (1/3)) «λs. a s = Heads»

(proof)

2.1.5 Properties of Expectations

The probabilities of independent events combine as usual, by multiplying: The chance of getting heads on two separate coins is (1::'a) / (4::'a).

definition
flip-b :: real ⇒ coins prog
where
flip-b p = b := (λ-. Heads) (λs. p)⊕ b := (λ-. Tails)

lemma
(λs. 1/4) = wp (flip-a (1/2) △ flip-b (1/2)) «λs. a s = Heads ∧ b s = Heads»

(proof)

If, rather than two coins, we use two dice, we can make some slightly more involved calculations. We see that the weakest pre-expectation of the value on the face of the die after rolling is its expected value in the initial state, which justifies the use of the term expectation.

record dice =
    red :: nat
    blue :: nat

definition Puniform :: 'a set ⇒ ('a ⇒ real)
where \( P\text{uniform} \, S = (\lambda \, x \, . \, \text{if } x \in S \text{ then } 1 / \text{card } S \text{ else } 0) \)

**lemma** \( P\text{uniform-in} \):
\[ x \in S \implies P\text{uniform} \, S \, x = 1 / \text{card } S \]
\( \langle \text{proof} \rangle \)

**lemma** \( P\text{uniform-out} \):
\[ x \notin S \implies P\text{uniform} \, S \, x = 0 \]
\( \langle \text{proof} \rangle \)

**lemma** supp-\( P\text{uniform} \):
\[ \text{finite } S \implies \text{supp} \, (P\text{uniform} \, S) = S \]
\( \langle \text{proof} \rangle \)

The expected value of a roll of a six-sided die is \((7::'a) / (2::'a)\):

**lemma**
\[ (\lambda \, s \, . \, 7 / 2) = \text{wp} \, ((\text{bind } \, v \, \text{at } (\lambda \, s \, . \, \text{Puniform} \, \{1..6\} \, v) \, \text{in } \text{red} \, := \, (\lambda \, \cdot \, v)) \, \text{red}) \]
\( \langle \text{proof} \rangle \)

The expectations of independent variables add:

**lemma**
\[ (\lambda \, s \, . \, 7) = \text{wp} \, (((\text{bind } \, v \, \text{at } (\lambda \, s \, . \, \text{Puniform} \, \{1..6\} \, v) \, \text{in } \text{red} \, := \, (\lambda \, \cdot \, v)) \, ;;\]
\[ \quad (\text{bind } \, v \, \text{at } (\lambda \, s \, . \, \text{Puniform} \, \{1..6\} \, v) \, \text{in } \text{blue} \, := \, (\lambda \, \cdot \, v))) \]
\[ \quad (\lambda \, s \, . \, \text{red } s + \text{blue } s) \]
\( \langle \text{proof} \rangle \)

end

### 2.2 Loops

**theory** LoopExamples imports ..;/pGCL begin

Reasoning about loops in pGCL is mostly familiar, in particular in the use of invariants. Proving termination for truly probabilistic loops is slightly different: We appeal to a 0–1 law to show that the loop terminates with probability 1. In our semantic model, terminating with certainty and with probability 1 are exactly equivalent.

#### 2.2.1 Guaranteed Termination

We start with a completely classical loop, to show that standard techniques apply. Here, we have a program that simply decrements a counter until it hits zero:

**definition** countdown :: int prog

**where**
\[ \text{countdown} = \text{do } (\lambda \, x \, . \, 0 < x) \implies \text{Apply} \, (\lambda \, s \, . \, s - 1) \, \text{od} \]
Clearly, this loop will only terminate from a state where \((0::'a) \leq x\). This is, in fact, also a loop invariant.

**definition** \(\text{inv-count} :: \text{int} \Rightarrow \text{bool}\)

**where**

\[
\text{inv-count} = (\lambda x. \ 0 \leq x)
\]

Read \(\text{wp-inv} \ G \ \text{body} \ I\) as: \(I\) is an invariant of the loop \(\mu x. \ \text{body} ;; \ x \ « \ G » \oplus \ \text{Skip}\), or \(« \ G » \ &\& \ I \vdash \text{wp} \ \text{body} \ I\).

**lemma** \(\text{wp-inv-count}:\)

\[
\text{wp-inv} (\lambda x. \ 0 < x) \ (\text{Apply} (\lambda s. \ s - 1)) \ « \text{inv-count}»
\]

(proof)

This example is contrived to give us an obvious variant, or measure function: the counter itself.

**lemma** \(\text{term-countdown}:\)

\[
« \text{inv-count}» \vdash \text{wp} \ \text{countdown} (\lambda s. \ 1)
\]

(proof)

### 2.2.2 Probabilistic Termination

Loops need not terminate deterministically: it is sufficient to terminate with probability 1. Here we show the intuitively obvious result that by flipping a coin repeatedly, you will eventually see heads.

**type-synonym** \(\text{coin} = \text{bool}\)

**definition** \(\text{Heads} = \text{True}\)

**definition** \(\text{Tails} = \text{False}\)

**definition**

\[
\text{flip} :: \text{coin prog}
\]

**where**

\[
\text{flip} = \text{Apply} (\lambda -. \ \text{Heads}) (\lambda s. \ 1/2) \oplus \ \text{Apply} (\lambda -. \ \text{Tails})
\]

We can’t define a measure here, as we did previously, as neither of the two possible states guarantee termination.

**definition**

\[
\text{wait-for-heads} :: \text{coin prog}
\]

**where**

\[
\text{wait-for-heads} = \text{do} ((\neq) \ \text{Heads}) \rightarrow \text{flip} \ \text{od}
\]

Nonetheless, we can show termination .

**lemma** \(\text{wait-for-heads-term}:\)

\[
\lambda s. \ 1 \vdash \text{wp} \ \text{wait-for-heads} (\lambda s. \ 1)
\]

(proof)

end
CHAPTER 2. INTRODUCTION TO PGCL

2.3 The Monty Hall Problem

theory Monty imports ../pGCL begin

We now tackle a more substantial example, allowing us to demonstrate the tools for compositional reasoning and the use of invariants in non-recursive programs. Our example is the well-known Monty Hall puzzle in statistical inference [Selvin, 1975].

The setting is a game show: There is a prize hidden behind one of three doors, and the contestant is invited to choose one. Once the guess is made, the host than opens one of the remaining two doors, revealing a goat and showing that the prize is elsewhere. The contestent is then given the choice of switching their guess to the other unopened door, or sticking to their first guess.

The puzzle is whether the contestant is better off switching or staying put; or indeed whether it makes a difference at all. Most people’s intuition suggests that it make no difference, whereas in fact, switching raises the chance of success from 1/3 to 2/3.

2.3.1 The State Space

The game state consists of the prize location, the guess, and the clue (the door the host opens). These are not constrained a priori to the range \{1, 2, 3\}, but are simply natural numbers: We instead show that this is in fact an invariant.

record game =
  prize :: nat
  guess :: nat
  clue :: nat

The victory condition: The player wins if they have guessed the correct door, when the game ends.

definition player-wins :: game ⇒ bool
where player-wins g ≡ guess g = prize g

Invariants

We prove explicitly that only valid doors are ever chosen.

definition inv-prize :: game ⇒ bool
where inv-prize g ≡ prize g ∈ \{1,2,3\}

definition inv-clue :: game ⇒ bool
where inv-clue g ≡ clue g ∈ \{1,2,3\}

definition inv-guess :: game ⇒ bool
where inv-guess g ≡ guess g ∈ \{1,2,3\}
2.3. THE MONTY HALL PROBLEM

2.3.2 The Game

Hide the prize behind door \( D \).

definition hide-behind :: nat ⇒ game prog
where hide-behind \( D \) ≡ Apply (prize-update (λx. \( D \)))

Choose door \( D \).

definition guess-behind :: nat ⇒ game prog
where guess-behind \( D \) ≡ Apply (guess-update (λx. \( D \)))

Open door \( D \) and reveal what’s behind.

definition open-door :: nat ⇒ game prog
where open-door \( D \) ≡ Apply (clue-update (λx. \( D \)))

Hide the prize behind door 1, 2 or 3, demonically i.e. according to any probability distribution (or none).

definition hide-prize :: game prog
where hide-prize ≡ hide-behind 1 low hide-behind 2 low hide-behind 3

Guess uniformly at random.

definition make-guess :: game prog
where make-guess ≡ guess-behind 1 (\( \lambda s \). \( 1/3 \)) ⊕

guess-behind 2 (\( \lambda s \). \( 1/2 \)) ⊕ guess-behind 3

Open one of the two doors that doesn’t hide the prize.

definition reveal :: game prog
where reveal ≡ \( \lambda d \in (\lambda s. \{1,2,3\} - \{\text{prize s, guess s}\}) \). open-door \( d \)

Switch your guess to the other unopened door.

definition switch-guess :: game prog
where switch-guess ≡ \( \lambda d \in (\lambda s. \{1,2,3\} - \{\text{clue s, guess s}\}) \). guess-behind \( d \)

The complete game, either with or without switching guesses.

definition monty :: bool ⇒ game prog
where
  monty switch ≡ hide-prize ;;
  make-guess ;;
  reveal ;;
  (if switch then switch-guess else Skip)

2.3.3 A Brute Force Solution

For sufficiently simple programs, we can calculate the exact weakest pre-expectation by unfolding.

lemma eval-win[simp]:
  \( p = g \implies \langle \text{player-wins} \rangle (s| \text{prize} := p, \text{guess} := g, \text{clue} := c) \rangle = 1 \)
⟨proof⟩

**Lemma** `eval-loss[simp]`:

\[ p \neq g \implies \text{«player-wins»} (s|\ prize := p, guess := g, clue := c |) = 0 \]

⟨proof⟩

If they stick to their guns, the player wins with \( p = \frac{1}{3} \).

**Lemma** `wp-monty-noswitch`:

\[ (λs. \frac{1}{3}) = \text{wp } (\text{monty False}) \text{«player-wins»} \]

⟨proof⟩

**Lemma** `swap-upd`:

\[ s|\ prize := p, clue := c, guess := g | = s|\ prize := p, guess := g, clue := c | \]

⟨proof⟩

If they switch, they win with \( p = \frac{2}{3} \). Brute force here takes longer, but is still feasible. On larger programs, this will rapidly become impossible, as the size of the terms (generally) grows exponentially with the length of the program.

**Lemma** `wp-monty-switch-bruteforce`:

\[ (λs. \frac{2}{3}) = \text{wp } (\text{monty True}) \text{«player-wins»} \]

⟨proof⟩

### 2.3.4 A Modular Approach

We can solve the problem more efficiently, at the cost of a little more user effort, by breaking up the problem and annotating each step of the game separately. While this is not strictly necessary for this program, it will scale to larger examples, as the work in annotation only increases linearly with the length of the program.

**Healthiness**

We first establish healthiness for each step. This follows straightforwardly by applying the supplied rulesets.

**Lemma** `wd-hide-prize`:

```
well-def hide-prize
⟨proof⟩
```

**Lemma** `wd-make-guess`:

```
well-def make-guess
⟨proof⟩
```

**Lemma** `wd-reveal`:

```
well-def reveal
⟨proof⟩
```
2.3. THE MONTY HALL PROBLEM

**lemma** wd-switch-guess:
  well-def switch-guess
  ⟨proof⟩

**lemmas** monty-healthy =
  wd-switch-guess wd-reveal wd-make-guess wd-hide-prize

**Annotations**

We now annotate each step individually, and then combine them to produce an annotation for the entire program.

hide-prize chooses a valid door.

**lemma** wp-hide-prize:
  \((\lambda s. 1) \vdash \wp \text{hide-prize} \ «\text{inv-prize}»\)
  ⟨proof⟩

Given the prize invariant, make-guess chooses a valid door, and guesses incorrectly with probability at least 2/3.

**lemma** wp-make-guess:
  \((\lambda s. 2/3 \ast \ «\lambda g. \text{inv-prize } g» \ s) \vdash \wp \text{make-guess} \ «\lambda g. \text{guess } g \neq \text{prize } g \land \text{inv-prize } g \land \text{inv-guess } g»\)
  ⟨proof⟩

**lemma** last-one:
  assumes \(a \neq b\) and \(a \in \{1::\text{nat},2,3\}\) and \(b \in \{1,2,3\}\)
  shows \(\exists!c. \{1,2,3\} - \{b,a\} = \{c\}\)
  ⟨proof⟩

Given the composed invariants, and an incorrect guess, reveal will give a clue that is neither the prize, nor the guess.

**lemma** wp-reveal:
  \(«\lambda g. \text{guess } g \neq \text{prize } g \land \text{inv-prize } g \land \text{inv-guess } g» \vdash \wp \text{reveal} \ «\lambda g. \text{guess } g \neq \text{prize } g \land \text{clue } g \neq \text{prize } g \land \text{clue } g \neq \text{guess } g \land \text{inv-prize } g \land \text{inv-guess } g \land \text{inv-clue } g»\)
  (is \(?X \vdash \wp \text{reveal} \ ?Y\))
  ⟨proof⟩

Showing that the three doors are all district is a largeish first-order problem, for which sledgehammer gives us a reasonable script.

**lemma** distinct-game:
  \[
  [ \text{guess } g \neq \text{prize } g; \text{clue } g \neq \text{prize } g; \text{clue } g \neq \text{guess } g; \\
  \text{inv-prize } g; \text{inv-guess } g; \text{inv-clue } g ] \implies \\
  \{1, 2, 3\} = \{\text{guess } g, \text{prize } g, \text{clue } g\}
  \]
  ⟨proof⟩
Given the invariants, switching from the wrong guess gives the right one.

**Lemma wp-switch-guess:**

\[
\lambda g. \text{guess } g \neq \text{prize } g \land \text{clue } g \neq \text{prize } g \land \text{clue } g \neq \text{guess } g \land \text{inv-prize } g \land \text{inv-guess } g \land \text{inv-clue } g \vdash \text{wp switch-guess player-wins}
\]

Given componentwise specifications, we can glue them together with calculational reasoning to get our result.

**Lemma wp-monty-switch-modular:**

\[
(\lambda s. 2/3) \vdash \text{wp (monty True) player-wins}
\]

**Using the VCG**

**Lemmas** scaled-hide = wp-scale[OF wp-hide-prize, simplified]

Alternatively, the VCG will get this using the same annotations.

**Lemma wp-monty-switch-vcg:**

\[
(\lambda s. 2/3) \vdash \text{wp (monty True) player-wins}
\]

end
Chapter 3

Semantic Structures

3.1 Expectations

theory Expectations imports Misc begin type-synonym 's expect = 's ⇒ real

Expectations are a real-valued generalisation of boolean predicates: An expectation on state 's is a function 's ⇒ real. A predicate P on 's is embedded as an expectation by mapping True to 1 and False to 0. Under this embedding, implication becomes comparison, as the truth tables demonstrate:

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>a → b</th>
<th>x</th>
<th>y</th>
<th>x ≤ y</th>
</tr>
</thead>
<tbody>
<tr>
<td>F</td>
<td>F</td>
<td>T</td>
<td>0</td>
<td>0</td>
<td>T</td>
</tr>
<tr>
<td>F</td>
<td>T</td>
<td>T</td>
<td>0</td>
<td>1</td>
<td>T</td>
</tr>
<tr>
<td>T</td>
<td>F</td>
<td>F</td>
<td>1</td>
<td>0</td>
<td>F</td>
</tr>
<tr>
<td>T</td>
<td>T</td>
<td>T</td>
<td>1</td>
<td>1</td>
<td>T</td>
</tr>
</tbody>
</table>

For probabilistic automata, an expectation gives the current expected value of some expression, if it were to be evaluated in the final state. For example, consider the automaton of Figure 3.1, with transition probabilities affixed to edges. Let P b = 2.0 and P c = 3.0. Both states b and c are final (accepting) states, and thus the ‘final expected value’ of P in state b is 2.0 and in state

![Figure 3.1: A probabilistic automaton](image-url)
c is 3.0. The expected value from state \( a \) is the weighted sum of these, or 
\[0.7 \times 2.0 + 0.3 \times 3.0 = 2.3.\]
All expectations must be non-negative and bounded i.e. \( \forall s. 0 \leq P \ s \) and \( \exists b. \forall s. P \ s \leq b \). Note that although every expectation must have a bound, there is no bound on all expectations; In particular, the following series has no global bound, although each element is clearly bounded:

\[P_i = \lambda s. \ i \quad \text{where} \ i \in \mathbb{N}\]

### 3.1.1 Bounded Functions

**Definition**  
\[
\text{bounded-by} :: \text{real} \Rightarrow (\text{'a} \Rightarrow \text{real}) \Rightarrow \text{bool}
\]

**Where**  
\[
\text{bounded-by} \ b \ P \equiv \forall x. \ P \ x \leq \ b
\]

By instantiating the classical reasoner, both establishing and appealing to boundedness is largely automatic.

**Lemma**  
\[
\text{bounded-byI}[\text{intro}]:
\]
\[
\left[ \left[ \forall x. \ P \ x \leq \ b \right] \implies \text{bounded-by} \ b \ P \right]
\]

(\text{proof})

**Lemma**  
\[
\text{bounded-byI2}[\text{intro}]:
\]
\[
P \leq (\lambda s. \ b) \implies \text{bounded-by} \ b \ P
\]

(\text{proof})

**Lemma**  
\[
\text{bounded-byD}[\text{dest}]:
\]
\[
\text{bounded-by} \ b \ P \implies \ P \ x \leq \ b
\]

(\text{proof})

**Lemma**  
\[
\text{bounded-byD2}[\text{dest}]:
\]
\[
\text{bounded-by} \ b \ P \implies P \leq (\lambda s. \ b)
\]

(\text{proof})

A function is bounded if there exists at least one upper bound on it.

**Definition**  
\[
\text{bounded} :: (\text{'a} \Rightarrow \text{real}) \Rightarrow \text{bool}
\]

**Where**  
\[
\text{bounded} \ P \equiv (\exists b. \ \text{bounded-by} \ b \ P)
\]

In the reals, if there exists any upper bound, then there must exist a least upper bound.

**Definition**  
\[
\text{bound-of} :: (\text{'a} \Rightarrow \text{real}) \Rightarrow \text{real}
\]

**Where**  
\[
\text{bound-of} \ P \equiv \text{Sup} \ (P \cdot \text{UNIV})
\]

**Lemma**  
\[
\text{bounded-bdd-above}[\text{intro}]:
\]
\[
\text{assumes} \ bP; \text{bounded} \ P
\]

**Shows**  
\[
\text{bdd-above} \ (\text{range} \ P)
\]

(\text{proof})

The least upper bound has the usual properties:
3.1. EXPECTATIONS

lemma bound-of-least[intro]:
  assumes bP: bounded-by b P
  shows bound-of P ≤ b
  ⟨proof⟩

lemma bounded-by-bound-of[intro]:
  fixes P::'a ⇒ real
  assumes bP: bounded P
  shows bounded-by (bound-of P) P
  ⟨proof⟩

lemma bound-of-greater[intro]:
  bounded P ⇒ P x ≤ bound-of P
  ⟨proof⟩

lemma bounded-by-mono:
  [ bounded-by a P; a ≤ b ] ⇒ bounded-by b P
  ⟨proof⟩

lemma bounded-by-imp-bounded[intro]:
  bounded-by b P ⇒ bounded P
  ⟨proof⟩

This is occasionally easier to apply:

lemma bounded-by-bound-of-alt:
  [ bounded P; bound-of P = a ] ⇒ bounded-by a P
  ⟨proof⟩

lemma bounded-const[simp]:
  bounded (λx. c)
  ⟨proof⟩

lemma bounded-by-const[intro]:
  c ≤ b ⇒ bounded-by b (λx. c)
  ⟨proof⟩

lemma bounded-by-mono-alt[intro]:
  [ bounded-by b Q; P ≤ Q ] ⇒ bounded-by b P
  ⟨proof⟩

lemma bound-of-const[simp, intro]:
  bound-of (λx. c) = (c::real)
  ⟨proof⟩

lemma bound-of-le1:
  assumes ∃x. P x ≤ (c::real)
  shows bound-of P ≤ c
  ⟨proof⟩
CHAPTER 3. SEMANTIC STRUCTURES

**Lemma** bound-of-mono[intro]:
\[ P \leq Q; \text{bounded } P; \text{bounded } Q \implies \text{bound-of } P \leq \text{bound-of } Q \]
⟨proof⟩

**Lemma** bounded-by-o[intro,simp]:
\[ \forall b. \text{bounded-by } b \ P \implies \text{bounded-by } b \ (P \circ f) \]
⟨proof⟩

**Lemma** le-bound-of[intro]:
\[ \forall x. \text{bounded } f \implies f \ x \leq \text{bound-of } f \]
⟨proof⟩

### 3.1.2 Non-Negative Functions.

The definitions for non-negative functions are analogous to those for bounded functions.

**Definition**
\[ \text{nneg} :: (\forall a \Rightarrow b:\{\text{zero,order}\}) \Rightarrow \text{bool} \]
where
\[ \text{nneg} \ P \longleftrightarrow (\forall x. \ 0 \leq P \ x) \]

**Lemma** nnegI[intro]:
\[ \[ \forall x. \ 0 \leq P \ x \] \implies \text{nneg} \ P \]
⟨proof⟩

**Lemma** nnegI2[intro]:
\[ (\lambda s. \ 0) \leq P \implies \text{nneg} \ P \]
⟨proof⟩

**Lemma** nnegD[dest]:
\[ \text{nneg} \ P \implies 0 \leq P \ x \]
⟨proof⟩

**Lemma** nnegD2[dest]:
\[ \text{nneg} \ P \implies (\lambda s. \ 0) \leq P \]
⟨proof⟩

**Lemma** nneg-bdd-below[intro]:
\[ \text{nneg} \ P \implies \text{bdd-below} \ (\text{range } P) \]
⟨proof⟩

**Lemma** nneg-const[iff]:
\[ \text{nneg} \ (\lambda x. \ c) \longleftrightarrow 0 \leq c \]
⟨proof⟩

**Lemma** nneg-o[intro,simp]:
\[ \text{nneg} \ P \implies \text{nneg} \ (P \circ f) \]
⟨proof⟩
lemma nneg-bound-nneg[intro]:
[ bounded P; nneg P ] \implies 0 \leq \text{bound-of} P
(proof)

lemma nneg-bounded-by-nneg[dest]:
[ bounded-by b P; nneg P ] \implies 0 \leq (b::real)
(proof)

lemma bounded-by-nneg[dest]:
fixes P :: 's \Rightarrow real
shows [ bounded-by b P; nneg P ] \implies 0 \leq b
(proof)

3.1.3 Sound Expectations

definition sound :: ('s \Rightarrow real) \Rightarrow bool
where sound P \equiv bounded P \land nneg P

Combining nneg and Expectations.bounded, we have sound expectations. We set up the classical reasoner and the simplifier, such that showing soundness, or deriving a simple consequence (e.g. sound P \implies 0 \leq P s) will usually follow by blast, force or simp.

lemma soundI:
[ bounded P; nneg P ] \implies sound P
(proof)

lemma soundI2[intro]:
[ bounded-by b P; nneg P ] \implies sound P
(proof)

lemma sound-bounded[dest]:
sound P \implies bounded P
(proof)

lemma sound-nneg[dest]:
sound P \implies nneg P
(proof)

lemma bound-of-sound[intro]:
assumes sP: sound P
shows 0 \leq \text{bound-of} P
(proof)

This proof demonstrates the use of the classical reasoner (specifically blast), to both introduce and eliminate soundness terms.

lemma sound-sum[simp,intro]:
assumes sP: sound P and sQ: sound Q
shows sound (\lambda s. P s + Q s)
(proof)
lemma mult-sound:
  assumes sP: sound P and sQ: sound Q
  shows sound (λs. P s * Q s)
⟨proof⟩

lemma div-sound:
  assumes sP: sound P and cpos: 0 < c
  shows sound (λs. P s / c)
⟨proof⟩

lemma tminus-sound:
  assumes sP: sound P and nnec: 0 ≤ c
  shows sound (λs. P s ⊖ c)
⟨proof⟩

lemma const-sound:
  0 ≤ c =⇒ sound (λs. c)
⟨proof⟩

lemma sound-o[intro,simp]:
  sound P =⇒ sound (P o f)
⟨proof⟩

lemma sc-bounded-by[intro,simp]:
  [sound P; 0 ≤ c] =⇒ bounded-by (c * bound-of P) (λx. c * P x)
⟨proof⟩

lemma sc-bounded[intro,simp]:
  assumes sP: sound P and pos: 0 ≤ c
  shows bounded (λx. c * P x)
⟨proof⟩

lemma sc-bound[simp]:
  assumes sP: sound P
  and nnec: 0 ≤ c
  shows c * bound-of P = bound-of (λx. c * P x)
⟨proof⟩

lemma sc-sound:
  [sound P; 0 ≤ c] =⇒ sound (λs. c * P s)
⟨proof⟩

lemma bounded-by-mult:
  assumes sP: sound P and bP: bounded-by a P
  and sQ: sound Q and bQ: bounded-by b Q
  shows bounded-by (a * b) (λs. P s * Q s)
⟨proof⟩
3.1. EXPECTATIONS

lemma bounded-by-add:
  fixes $P :: s \Rightarrow \text{real}$ and $Q$
  assumes $bP$: bounded-by $a$ $P$
  and $bQ$: bounded-by $b$ $Q$
  shows bounded-by $(a + b) (\lambda s. P s + Q s)$
⟨proof⟩

lemma sound-unit[intro,simp]:
  sound $(\lambda s. 1)$
⟨proof⟩

lemma unit-mult[intro]:
  assumes $sP$: sound $P$ and $bP$: bounded-by 1 $P$
  and $sQ$: sound $Q$ and $bQ$: bounded-by 1 $Q$
  shows bounded-by 1 $(\lambda s. P s \ast Q s)$
⟨proof⟩

lemma sum-sound:
  assumes $sP$: $\forall x \in S. \text{sound } (P x)$
  shows sound $(\lambda s. \sum x \in S. P x s)$
⟨proof⟩

3.1.4 Unitary expectations

A unitary expectation is a sound expectation that is additionally bounded by one. This is the domain on which the liberal (partial correctness) semantics operates.

definition unitary :: $'s expect \Rightarrow \text{bool}$
where unitary $P \iff \text{sound } P \land \text{bounded-by 1 } P$

lemma unitaryI[intro]:
  $[ \text{sound } P; \text{bounded-by 1 } P ] \Rightarrow \text{unitary } P$
⟨proof⟩

lemma unitaryI2:
  $[ \text{neg } P; \text{bounded-by 1 } P ] \Rightarrow \text{unitary } P$
⟨proof⟩

lemma unitary-sound[dest]:
  unitary $P \Rightarrow \text{sound } P$
⟨proof⟩

lemma unitary-bound[dest]:
  unitary $P \Rightarrow \text{bounded-by 1 } P$
⟨proof⟩

3.1.5 Standard Expectations

definition
embed-bool :: (’s ⇒ bool) ⇒ ’s ⇒ real (« - » 1000)

where

«P» ≡ (λs. if P s then 1 else 0)

Standard expectations are the embeddings of boolean predicates, mapping False to 0 and True to 1. We write «P» rather than [P] (the syntax employed by McIver and Morgan [2004]) for boolean embedding to avoid clashing with the HOL syntax for lists.

lemma embed-bool-nneg: [simp, intro]:
nneg «P»
⟨proof⟩

lemma embed-bool-bounded-by-1[simp, intro]:
bounded-by 1 «P»
⟨proof⟩

lemma embed-bool-bounded[simp, intro]:
bounded «P»
⟨proof⟩

Standard expectations have a number of convenient properties, which mostly follow from boolean algebra.

lemma embed-bool-idem: «P» s ∗ «P» s = «P» s
⟨proof⟩

lemma eval-embed-true[simp]:
P s ⇒ «P» s = 1
⟨proof⟩

lemma eval-embed-false[simp]:
¬P s ⇒ «P» s = 0
⟨proof⟩

lemma embed-ge-0[simp, intro]:
0 ≤ «G» s
⟨proof⟩

lemma embed-le-1 [simp, intro]: «G» s ≤ 1
⟨proof⟩

lemma embed-le-1-alt[simp, intro]:
0 ≤ 1 - «G» s
⟨proof⟩

lemma expect-1-I:
P x ⇒ 1 ≤ «P» x
⟨proof⟩
Negating a predicate has the expected effect in its embedding as an expectation:

**definition** negate :: ('s ⇒ bool) ⇒ 's ⇒ bool (N)
**where** negate P = (λs. ¬ P s)

**lemma** negateI:
¬ P s ⇒ N P s
⟨proof⟩

**lemma** embed-split:
f s = «P» s * f s + «N P» s * f s
⟨proof⟩

**lemma** negate-embed:
«N P» s = 1 − «P» s
⟨proof⟩

**lemma** eval-nembed-true[simp]:
P s ⇒ «N P» s = 0
⟨proof⟩

**lemma** eval-nembed-false[simp]:
¬P s ⇒ «N P» s = 1
⟨proof⟩

**lemma** negate-Not[simp]:
N Not = (λx. x)
⟨proof⟩

**lemma** negate-negate[simp]:
N (N P) = P
⟨proof⟩

**lemma** embed-bool-cancel:
«G» s * «N G» s = 0
⟨proof⟩
3.1.6 Entailment

Entailment on expectations is a generalisation of that on predicates, and is defined by pointwise comparison:

**abbreviation** `entails :: (′s ⇒ real) ⇒ (′s ⇒ real) ⇒ bool (· ⊬ · 50)`

where `P ⊬ Q ≡ P ≤ Q`

**lemma** `entailsI[intro]`:

\[ \forall s. P s ≤ Q s \Rightarrow P ⊬ Q \]

⟨proof⟩

**lemma** `entailsD[dest]`:

\[ P ⊬ Q ⇒ P s ≤ Q s \]

⟨proof⟩

**lemma** `eq-entails[intro]`:

\[ P = Q ⇒ P ⊬ Q \]

⟨proof⟩

**lemma** `entails-trans[trans]`:

\[ [ P ⊬ Q; Q ⊬ R ] ⇒ P ⊬ R \]

⟨proof⟩

For standard expectations, both notions of entailment coincide. This result justifies the above claim that our definition generalises predicate entailment:

**lemma** `implies-entails`:

\[ [ \forall s. P s ⇒ Q s ] ⇒ «P» ⊬ «Q» \]

⟨proof⟩

**lemma** `entails-implies`:

\[ ∀ s. [ «P» ⊬ «Q»; P s ] ⇒ Q s \]

⟨proof⟩

3.1.7 Expectation Conjunction

**definition**

`pconj :: real ⇒ real ⇒ real (infixl & 71)`

where `p & q ≡ p + q ⊙ 1`

**definition**

`exp-conj :: (′s ⇒ real) ⇒ (′s ⇒ real) ⇒ (′s ⇒ real) (infixl && 71)`

where `a && b ≡ λs. (a s && b s)`

Expectation conjunction likewise generalises (boolean) predicate conjunction. We show that the expected properties are preserved, and instantiate both the classical reasoner, and the simplifier (in the case of associativity and commutativity).
3.1. EXPECTATIONS

lemma pconj-lzero[intro,simp]:
\[ b \leq 1 \implies 0 \land b = 0 \]
\(\langle \text{proof} \rangle\)

lemma pconj-rzero[intro,simp]:
\[ b \leq 1 \implies b \land 0 = 0 \]
\(\langle \text{proof} \rangle\)

lemma pconj-lone[intro,simp]:
\[ 0 \leq b \implies 1 \land b = b \]
\(\langle \text{proof} \rangle\)

lemma pconj-rone[intro,simp]:
\[ 0 \leq b \implies b \land 1 = b \]
\(\langle \text{proof} \rangle\)

lemma pconj-bconj:
\[ "a" s \land "b" s = "\lambda s. a s \land b s" s \]
\(\langle \text{proof} \rangle\)

lemma pconj-comm[ac-simps]:
\[ a \land b = b \land a \]
\(\langle \text{proof} \rangle\)

lemma pconj-associ:
\[ a \land (b \land c) = (a \land b) \land c \]
\(\langle \text{proof} \rangle\)

lemma pconj-mono:
\[ a \land c \leq b \land d \]
\(\langle \text{proof} \rangle\)

lemma pconj-nneg[intro,simp]:
\[ 0 \leq a \land b \]
\(\langle \text{proof} \rangle\)

lemma min-pconj:
\[ (\min a b) \land (\min c d) \leq \min (a \land c) (b \land d) \]
\(\langle \text{proof} \rangle\)

lemma pconj-less-one[simp]:
\[ a + b < 1 \implies a \land b = 0 \]
\(\langle \text{proof} \rangle\)

lemma pconj-ge-one[simp]:
\[ 1 \leq a + b \implies a \land b = a + b - 1 \]
\(\langle \text{proof} \rangle\)
3.1.8 Rules Involving Conjunction.

**Lemma exp-conj-mono-left:**
\[ P \vdash Q \text{ implies } P \&\& R \vdash Q \&\& R \]
⟨proof⟩

**Lemma exp-conj-mono-right:**
\[ Q \vdash R \text{ implies } P \&\& Q \vdash P \&\& R \]
⟨proof⟩

**Lemma exp-conj-comm[ac-simps]:**
\[ a \&\& b = b \&\& a \]
⟨proof⟩

**Lemma exp-conj-bounded-by[intro,simp]:**
\begin{align*}
\text{assumes } & bP: \text{ bounded-by } 1 P \\
\text{and } & bQ: \text{ bounded-by } 1 Q \\
\text{shows } & \text{ bounded-by } 1 (P \&\& Q) \\
\end{align*}
⟨proof⟩

**Lemma exp-conj-o-distrib[simp]:**
\[ (P \&\& Q) o f = (P o f) \&\& (Q o f) \]
⟨proof⟩

**Lemma exp-conj-assoc:**
\begin{align*}
\text{assumes } & \text{unitary } P \text{ and } Q \text{ and } R \\
\text{shows } & P \&\& (Q \&\& R) = (P \&\& Q) \&\& R \\
\end{align*}
⟨proof⟩

**Lemma exp-conj-top-left[simp]:**
\[ \text{sound } P \implies \langle \lambda s. \text{True} \rangle \&\& P = P \]
⟨proof⟩

**Lemma exp-conj-top-right[simp]:**
\[ \text{sound } P \implies P \&\& \langle \lambda s. \text{True} \rangle = P \]
⟨proof⟩

**Lemma exp-conj-idem[simp]:**
\[ \langle P \rangle \&\& \langle P \rangle = \langle P \rangle \]
⟨proof⟩

**Lemma exp-conj-nneg[intro,simp]:**
\[ (\lambda s. 0) \leq P \&\& Q \]
⟨proof⟩
3.1. EXPECTATIONS

**lemma** exp-conj-sound\([\text{intro},\text{simp}]\):
\begin{align*}
\text{assumes } & s-P: \text{sound } P \\
\text{and } & s-Q: \text{sound } Q \\
\text{shows } & \text{sound } (P \&\& Q)
\end{align*}
\langle proof \rangle

**lemma** exp-conj-rzero\([\text{simp}]\):
\begin{align*}
bounded-by \ 1 \ P \rightarrow P \&\& (\lambda s. \ 0) & = (\lambda s. \ 0)
\end{align*}
\langle proof \rangle

**lemma** exp-conj-1-right\([\text{simp}]\):
\begin{align*}
\text{assumes } & nn: \text{nneg } A \\
\text{shows } & A \&\& (\lambda-. \ 1) = A
\end{align*}
\langle proof \rangle

**lemma** exp-conj-std-split:
\begin{align*}
\« \lambda s. \ P s \land Q s \» & = \« P » \&\& \« Q »
\end{align*}
\langle proof \rangle

3.1.9 Rules Involving Entailment and Conjunction Together

Meta-conjunction distributes over expectation entailment, becoming expectation conjunction:

**lemma** entails-frame:
\begin{align*}
\text{assumes } & ePR: P \vdash \vdash R \\
\text{and } & eQS: Q \vdash \vdash S \\
\text{shows } & P \&\& Q \vdash \vdash R \&\& S
\end{align*}
\langle proof \rangle

This rule allows something very much akin to a case distinction on the pre-expectation.

**lemma** pentails-cases:
\begin{align*}
\text{assumes } & PQe: \forall x. \ P x \vdash Q x \\
\text{and } & exhaust: \forall s. \ \exists x. \ P (x s) \ s = 1 \\
\text{and } & framed: \forall x. \ P x \&\& R \vdash Q x \&\& S \\
\text{and } & sR: \text{sound } R \text{ and } sS: \text{sound } S \\
\text{and } & bQ: \ \forall x. \ \text{bounded-by } 1 (Q x) \\
\text{shows } & R \vdash \vdash S
\end{align*}
\langle proof \rangle

**lemma** unitary-bot\([\text{iff}]\):
\begin{align*}
\text{unitary } (\lambda s. \ 0::\text{real})
\end{align*}
\langle proof \rangle

**lemma** unitary-top\([\text{iff}]\):
\begin{align*}
\text{unitary } (\lambda s. \ 1::\text{real})
\end{align*}
\langle proof \rangle

**lemma** unitary-embed:[iff]:

\[
\text{unitary } \langle P \rangle
\]

(\text{proof})

**lemma** unitary-const:[iff]:

\[
[ 0 \leq c; c \leq 1 ] \Rightarrow \text{unitary } (\lambda s. c)
\]

(\text{proof})

**lemma** unitary-mult:

\text{assumes } uA: \text{unitary } A \text{ and } uB: \text{unitary } B

\text{shows } \text{unitary } (\lambda s. A \cdot B \cdot s)

(\text{proof})

**lemma** exp-conj-unitary:

\[
[ \text{unitary } P; \text{unitary } Q ] \Rightarrow \text{unitary } (P \&\& Q)
\]

(\text{proof})

**lemma** unitary-comp[simp]:

\text{unitary } P \Rightarrow \text{unitary } (P \circ f)

(\text{proof})

**lemmas** unitary-intros =

unitary-bot unitary-top unitary-embed unitary-mult exp-conj-unitary

unitary-comp unitary-const

**lemmas** sound-intros =

mult-sound div-sound const-sound sound-o sound-sum
tminus-sound sc-sound exp-conj-sound sum-sound

end

### 3.2 Expectation Transformers

**theory** Transformers \text{imports} Expectations begin type-synonym \('s\ trans = \('s\ expect \Rightarrow \('s\ expect)

Transformers are functions from expectations to expectations i.e. \((s \Rightarrow \text{real}) \Rightarrow ('s \Rightarrow \text{real})\).

The set of healthy transformers is the universe into which we place our semantic interpretation of pGCL programs. In its standard presentation, the healthiness condition for pGCL programs is sublinearity, for demonic programs, and superlinearity for angelic programs. We extract a minimal core property, consisting of monotonicity, feasibility and scaling to form our healthiness property, which holds across all programs. The additional components of sublinearity are broken out separately, and shown later. The two reasons for this are firstly to avoid the effort of establishing sub-(super-)linearity globally, and to allow us to define primitives whose sublinearity,
3.2. EXPECTATION TRANSFORMERS

and indeed healthiness, depend on context.

Consider again the automaton of Figure 3.1. Here, the effect of executing the automaton from its initial state (a) until it reaches some final state (b or c) is to transform the expectation on final states (P), into one on initial states, giving the expected value of the function on termination. Here, the transformation is linear: \( P_{\text{prior}}(a) = 0.7 \times P_{\text{post}}(b) + 0.3 \times P_{\text{post}}(c) \), but this need not be the case.

Consider the automaton of Figure 3.2. Here, we have extended that of Figure 3.1 with two additional states, d and e, and a pair of silent (unlabelled) transitions. From the initial state, e, this automaton is free to transition either to the original starting state (a), and thence behave exactly as the previous automaton did, or to d, which has the same set of available transitions, now with different probabilities. Where previously we could state that the automaton would terminate in state b with probability 0.7 (and in c with probability 0.3), this now depends on the outcome of the nondeterministic transition from e to either a or d. The most we can now say is that we must reach b with probability at least 0.5 (the minimum from either a or d) and c with at least probability 0.3. Note that these probabilities do not sum to one (although the sum will still always be less than one). The associated expectation transformer is now sub-linear: \( P_{\text{prior}}(e) = 0.5 \times P_{\text{post}}(b) + 0.3 \times P_{\text{post}}(c) \).

Finally, Figure 3.3 shows the other way in which strict sublinearity arises: divergence. This automaton transitions with probability 0.5 to state d, from which it never escapes. Once there, the probability of reaching any terminating state is zero, and thus the probability of terminating from the initial state (e) is no higher than 0.5. If it instead takes the edge to state a, we again see a self loop, and thus in theory an infinite trace. In this case, however, every time the automaton reaches state a, with probability 0.5 + 0.3 = 0.8, it transitions to a terminating state. An infinite trace of transitions \( a \to a \to \ldots \) thus has probability 0, and the automaton
terminates with probability 1. We formalise such probabilistic termination arguments in Section 4.11.

Having reached $a$, the automaton will proceed to $b$ with probability $0.5 \times (1/(0.5 + 0.3)) = 0.625$, and to $c$ with probability $0.375$. As $a$ is in turn reached half the time, the final probability of ending in $b$ is 0.3125, and in $c$, 0.1875, which sum to only 0.5. The remaining probability is that the automaton diverges via $d$. We view nondeterminism and divergence demonically: we take the least probability of reaching a given final state, and use it to calculate the expectation. Thus for this automaton, $P_{\text{prior}}(c) = 0.3125 \times P_{\text{post}}(b) + 0.1875 \times P_{\text{post}}(c)$. The end result is the same as for nondeterminism: a sublinear transformation (the weights sum to less than one).

The two outcomes are thus unified in the semantic interpretation, although as we will establish in Section 4.6, the two have slightly different algebraic properties.

This pattern holds for all pGCL programs: probabilistic choices are always linear, while struct sublinearity is introduced both nondeterminism and divergence.

Healthiness, again, is the combination of three properties: feasibility, monotonicity and scaling. Feasibility requires that a transformer take non-negative expectations to non-negative expectations, and preserve bounds. Thus, starting with an expectation bounded between 0 and some bound, $b$, after applying any number of feasible transformers, the result will still be bounded between 0 and $b$. This closure property allows us to treat expectations almost as a complete lattice. Specifically, for any $b$, the set of expectations bounded by $b$ is a complete lattice ($\bot = (\lambda s.0), \top = (\lambda s.b)$), and is closed under the action of feasible transformers, including $\sqcap$ and $\sqcup$, which are themselves feasible. We are thus able to define both least and greatest fixed points on this set, and thus give semantics to recursive programs built from feasible components.
3.2. EXPECTATION TRANSFORMERS

3.2.1 Comparing Transformers

Transformers are compared pointwise, but only on sound expectations. From the preorder so generated, we define equivalence by antisymmetry, giving a partial order.

**definition**

\textit{le-trans} :: \textit{'s trans} \Rightarrow \textit{'s trans} \Rightarrow \text{bool}

**where**

\textit{le-trans} \ t \ u \equiv \forall \ P. \ \text{sound} \ P \implies \ t \ P \leq \ u \ P

We also need to define relations restricted to unitary transformers, for the liberal (wlp) semantics.

**definition**

\textit{le-utrans} :: \textit{'s trans} \Rightarrow \textit{'s trans} \Rightarrow \text{bool}

**where**

\textit{le-utrans} \ t \ u \iff \forall \ P. \ \text{unitary} \ P \implies \ t \ P \leq \ u \ P

**lemma** \textit{le-transI}[intro]:

[ \forall P. \ \text{sound} \ P \implies \ t \ P \leq \ u \ P ] \implies \textit{le-trans} \ t \ u

**proof**

**lemma** \textit{le-utransI}[intro]:

[ \forall P. \ \text{unitary} \ P \implies \ t \ P \leq \ u \ P ] \implies \textit{le-utrans} \ t \ u

**proof**

**lemma** \textit{le-transD}[dest]:

[ \textit{le-trans} \ t \ u; \ \text{sound} \ P ] \implies t \ P \leq u \ P

**proof**

**lemma** \textit{le-utransD}[dest]:

[ \textit{le-utrans} \ t \ u; \ \text{unitary} \ P ] \implies t \ P \leq u \ P

**proof**

**lemma** \textit{le-trans-trans}[trans]:

[ \textit{le-trans} \ x \ y; \ \textit{le-trans} \ y \ z ] \implies \textit{le-trans} \ x \ z

**proof**

**lemma** \textit{le-utrans-trans}[trans]:

[ \textit{le-utrans} \ x \ y; \ \textit{le-utrans} \ y \ z ] \implies \textit{le-utrans} \ x \ z

**proof**

**lemma** \textit{le-trans-refl}[iff]:

\textit{le-trans} \ x \ x

**proof**

**lemma** \textit{le-utrans-refl}[iff]:

\textit{le-utrans} \ x \ x

**proof**
**CHAPTER 3. SEMANTIC STRUCTURES**

**Lemma** `le-trans-le-utrans[dest]`:
\[
\text{le-trans } t \; u \implies \text{le-utrans } t \; u
\]

**Definition**
\[
\text{l-trans :: 's trans } \Rightarrow \; 's \; \text{trans } \Rightarrow \; \text{bool}
\]
**where**
\[

3.2.2 Healthy Transformers

Feasibility

definition feasible :: \( (\forall a \Rightarrow \text{real}) \Rightarrow (\forall a \Rightarrow \text{real}) \Rightarrow \text{bool} \)
where feasible \( t \) \longleftrightarrow \( \forall P. \text{bounded-by } b \ P \land \text{nneg } P \implies \text{bounded-by } b \ (t \ P) \land \text{nneg } (t \ P) \)

A feasible transformer preserves non-negativity, and bounds. A feasible transformer always takes its argument ‘closer to 0’ (or leaves it where it is). Note that any particular value of the expectation may increase, but no element of the new expectation may exceed any bound on the old. This is thus a relatively weak condition.

lemma feasibleI[intro]:
\[ \forall b. \ [ \text{bounded-by } b \ P; \text{nneg } P \] \implies \text{bounded-by } b \ (t \ P); \\
\forall b. \ [ \text{bounded-by } b \ P; \text{nneg } P \] \implies \text{nneg } (t \ P) \] \implies \text{feasible } t
\langle proof \rangle

lemma feasible-boundedD[dest]:
\[ \text{feasible } t; \text{bounded-by } b \ P; \text{nneg } P \] \implies \text{bounded-by } b \ (t \ P)
\langle proof \rangle

lemma feasible-nnegD[dest]:
3.2. EXPECTATION TRANSFORMERS

\[ [ \text{feasible } t; \text{bounded-by } b \ P; \ \text{nneq } P ] ] \Rightarrow \text{nneq } (t \ P) \]

\textit{lemma feasible-sound[dest]};
\[ [ \text{feasible } t; \text{sound } P ] ] \Rightarrow \text{sound } (t \ P) \]

\textit{lemma feasible-pr-0[simp]}:
- \text{fixes } t::(s \Rightarrow \text{real}) \Rightarrow (s \Rightarrow \text{real})
- \text{assumes } ft: \text{feasible } t
- \text{shows } t (\lambda x. \ 0) = (\lambda x. \ 0) \]

\textit{lemma feasible-id}:
- \text{feasible } (\lambda x. \ x)

\textit{lemma feasible-bounded-by[dest]}:
\[ [ \text{feasible } t; \text{sound } P; \text{bounded-by } b \ P ] ] \Rightarrow \text{bounded-by } b (t \ P) \]

\textit{lemma feasible-fixes-top}:
- \text{feasible } t \Rightarrow t (\lambda s. \ 1) \leq (\lambda s. \ (1::\text{real}))

\textit{lemma feasible-fixes-bot}:
- \text{assumes } ft: \text{feasible } t
- \text{shows } t (\lambda s. \ 0) = (\lambda s. \ 0) \]

\textit{lemma feasible-unitaryD[dest]}:
- \text{assumes } ft: \text{feasible } t \text{ and } uP: \text{unitary } P
- \text{shows } \text{unitary } (t \ P) \]

\textbf{Monotonicity}

\textit{definition}
- \text{mono-trans } :: ((s \Rightarrow \text{real}) \Rightarrow (s \Rightarrow \text{real})) \Rightarrow \text{bool}

\textit{where}
- \text{mono-trans } t \equiv \forall P \ Q. \ (\text{sound } P \land \text{sound } Q \land P \leq Q) \rightarrow t \ P \leq t \ Q

Monotonicity allows us to compose transformers, and thus model sequential computation. Recall the definition of predicate entailment (Section 3.1.6) as less-than-or-equal. The statement \( Q \vdash t R \) means that \( Q \) is everywhere below \( t R \). For standard expectations (Section 3.1.5), this simply means that \( Q \) implies \( t R \), the \textit{weakest precondition} of \( R \) under \( t \).

Given another, monotonic, transformer \( u \), we have that \( u Q \vdash u (t R) \), or that the weakest precondition of \( Q \) under \( u \) entails that of \( R \) under the
CHAPTER 3. SEMANTIC STRUCTURES

composition \( u \circ t \). If we additionally know that \( P \vdash u Q \), then by transitivity we have \( P \vdash u (t R) \). We thus derive a probabilistic form of the standard rule for sequential composition: 

\[
\begin{align*}
\text{mono-trans } t; \quad P \vdash u Q; \quad Q \vdash t R & \implies P \vdash u (t R) \\
\end{align*}
\]

**Lemma** \texttt{mono-transI} [\texttt{intro}]:

\[
\begin{align*}
\forall P, Q. \quad [\text{sound } P; \text{sound } Q; \ P \leq Q ] \implies t P \leq t Q & \implies \text{mono-trans } t
\end{align*}
\]

**Lemma** \texttt{mono-transD} [\texttt{dest}]:

\[
\begin{align*}
[ \text{mono-trans } t; \text{sound } P; \text{sound } Q; \ P \leq Q ] \implies t P \leq t Q
\end{align*}
\]

**Scaling**

A healthy transformer commutes with scaling by a non-negative constant.

**Definition** \texttt{scaling}:

\[
\begin{align*}
\text{scaling } : \ (('s \Rightarrow \text{real}) \Rightarrow ('s \Rightarrow \text{real})) \Rightarrow \text{bool}
\end{align*}
\]

**Where**

\[
\begin{align*}
\text{scaling } t & \equiv \forall P c x. \text{sound } P \land 0 \leq c \implies c \ast t P x = t (\lambda x. c \ast P x) x
\end{align*}
\]

The \texttt{scaling} and feasibility properties together allow us to treat transformers as a complete lattice, when operating on bounded expectations. The action of a transformer on such a bounded expectation is completely determined by its action on unitary expectations (those bounded by 1): \( t P s = \text{bound-of } P \ast t (\lambda s. P s / \text{bound-of } P) s \). Feasibility in turn ensures that the lattice of unitary expectations is closed under the action of a healthy transformer. We take advantage of this fact in Section 3.3, in order to define the fixed points of healthy transformers.

**Lemma** \texttt{scalingI} [\texttt{intro}]:

\[
\begin{align*}
\forall P c x. \text{sound } P; 0 \leq c \implies c \ast t P x = t (\lambda x. c \ast P x) x
\end{align*}
\]

**Lemma** \texttt{scalingD} [\texttt{dest}]:

\[
\begin{align*}
\text{scaling } t; \text{sound } P; 0 \leq c \implies c \ast t P x = t (\lambda x. c \ast P x) x
\end{align*}
\]

**Lemma** \texttt{right-scalingD}:

**Assumes** \( st: \text{scaling } t \)

**And** \( sP: \text{sound } P \)

**And** \( nnc: 0 \leq c \)

**Shows** \( t P s \ast c = t (\lambda s. P s \ast c) s \)

**Healthiness**

Healthy transformers are feasible and monotonic, and respect scaling
3.2. EXPECTATION TRANSFORMERS

**definition**

\[ \text{healthy} :: (\text{'s} \rightarrow \text{real}) \rightarrow (\text{'s} \rightarrow \text{real}) \rightarrow \text{bool} \]

**where**

\[ \text{healthy } t \leftrightarrow \text{feasible } t \land \text{mono-trans } t \land \text{scaling } t \]

**lemma** \text{healthyI[ intro ]} :

\[ \text{[ feasible } t; \text{ mono-trans } t; \text{ scaling } t ] \implies \text{ healthy } t \]

**lemmas** \text{ healthy-parts = healthyI[ OF feasibleI mono-transI scalingI ]}

**lemma** \text{ healthy-monoD[ dest ]} :

\[ \text{healthy } t \implies \text{ mono-trans } t \]

**lemmas** \text{ healthy-monoD2 = mono-transD[ OF healthy-monoD ]}

**lemma** \text{ healthy-feasibleD[ dest ]} :

\[ \text{healthy } t \implies \text{ feasible } t \]

**lemma** \text{ healthy-scalingD[ dest ]} :

\[ \text{healthy } t \implies \text{ scaling } t \]

**lemma** \text{ healthy-bounded-byD[ intro ]} :

\[ \text{[ healthy } t; \text{ bounded-by } b \ P; \text{ nneg } P ] \implies \text{ bounded-by } b \ (t \ P) \]

**lemma** \text{ healthy-bounded-byD2} :

\[ \text{[ healthy } t; \text{ bounded-by } b \ P; \text{ sound } P ] \implies \text{ bounded-by } b \ (t \ P) \]

**lemma** \text{ healthy-boundedD[ dest,simp ]} :

\[ \text{[ healthy } t; \text{ sound } P ] \implies \text{ bounded } (t \ P) \]

**lemma** \text{ healthy-nnegD[ dest,simp ]} :

\[ \text{[ healthy } t; \text{ sound } P ] \implies \text{ nneg } (t \ P) \]

**lemma** \text{ healthy-nnegD2[ dest,simp ]} :

\[ \text{[ healthy } t; \text{ bounded-by } b \ P; \text{ nneg } P ] \implies \text{ nneg } (t \ P) \]

**lemma** \text{ healthy-sound[ intro ]} :

\[ \text{[ healthy } t; \text{ sound } P ] \implies \text{ sound } (t \ P) \]
lemma healthy-unitary[intro]:
  \[ \text{healthy } t; \text{ unitary } P \] \implies \text{unitary } (t P) 
  \langle \text{proof} \rangle

lemma healthy-id[simp,intro!]:
  healthy id
  \langle \text{proof} \rangle

lemmas healthy-fxes-bot = feasible-fxes-bot[OF healthy-feasibleD]

Some additional results on le-trans, specific to healthy transformers.

lemma le-trans-bot[intro,simp]:
  healthy t \implies le-trans (\lambda P s. 0) t
  \langle \text{proof} \rangle

lemma le-trans-top[intro,simp]:
  healthy t \implies le-trans t (\lambda P s. \text{bound-of } P)
  \langle \text{proof} \rangle

lemma healthy-pr-bot[simp]:
  healthy t \implies t (\lambda s. 0) = (\lambda s. 0)
  \langle \text{proof} \rangle

The first significant result is that healthiness is preserved by equivalence:

lemma healthy-equivI:
  fixes t::('s \Rightarrow \text{real}) \Rightarrow 's \Rightarrow \text{real} and u
  assumes equiv: equiv-trans t u
  and healthy: healthy t
  shows healthy u
  \langle \text{proof} \rangle

lemma healthy-equiv:
  equiv-trans t u \implies healthy t \iff healthy u
  \langle \text{proof} \rangle

lemma healthy-scale:
  fixes t::('s \Rightarrow \text{real}) \Rightarrow 's \Rightarrow \text{real}
  assumes ht: healthy t and nc: 0 \leq c and bc: c \leq 1
  shows healthy (\lambda P s. c * t P s)
  \langle \text{proof} \rangle

lemma healthy-top[iff]:
  healthy (\lambda P s. \text{bound-of } P)
  \langle \text{proof} \rangle

lemma healthy-bot[iff]:
  healthy (\lambda P s. 0)
  \langle \text{proof} \rangle

This weaker healthiness condition is for the liberal (wlp) semantics. We
only insist that the transformer preserves unitarity (bounded by 1), and
drop scaling (it is unnecessary in establishing the lattice structure here,
unlike for the strict semantics).

**definition**

\[ \text{nearly-healthy} :: \left( (\forall s \Rightarrow \text{real}) \Rightarrow (\forall s \Rightarrow \text{real}) \right) \Rightarrow \text{bool} \]

**where**

\[ \text{nearly-healthy} \ t \longleftrightarrow (\forall P. \text{unitary } P \implies \text{unitary } (t\ P)) \land
\ (\forall P.Q. \text{unitary } P \implies \text{unitary } Q \implies P \vdash Q \implies t\ P \vdash t\ Q) \]

**lemma** nearly-healthy\[\text{intro}\] :

\[
\left[ \bigwedge P. \text{unitary } P \implies \text{unitary } (t\ P); \bigwedge P.Q. \left[ \bigwedge \text{unitary } P; \text{unitary } Q; P \vdash Q \right] \implies t\ P \vdash t\ Q \right] \implies \text{nearly-healthy } t
\]

**lemma** nearly-healthy-mono\[\text{dest}\] :

\[
\left[ \text{nearly-healthy } t; P \vdash Q; \text{unitary } P; \text{unitary } Q \right] \implies t\ P \vdash t\ Q
\]

**lemma** nearly-healthy-unitary\[\text{dest}\] :

\[
\left[ \text{nearly-healthy } t; \text{unitary } P \right] \implies \text{unitary } (t\ P)
\]

**lemma** healthy-nearly-healthy\[\text{dest}\] :

\[ \text{assumes } \text{ht}: \text{healthy } t \text{ shows } \text{nearly-healthy } t \]

**lemmas** nearly-healthy-id\[\text{iff}\] =

\[ \text{healthy-nearly-healthy}\{\text{OF healthy-id}, \text{unfolded id-def}\} \]

### 3.2.3 Sublinearity

As already mentioned, the core healthiness property (aside from feasibility and continuity) for transformers is sublinearity: The transformation of a quasi-linear combination of sound expectations is greater than the same combination applied to the transformation of the expectations themselves. The term \( x \ominus y \) represents truncated subtraction i.e. \( \max (x - y) (0::'a) \) (see Section 4.13.1).

**definition** sublinear ::

\[ \left( (\forall s \Rightarrow \text{real}) \Rightarrow (\forall s \Rightarrow \text{real}) \right) \Rightarrow \text{bool} \]

**where**

\[ \text{sublinear} \ t \longleftrightarrow (\forall a\ b\ c\ P\ Q\ s. \left( \text{sound } P \land \text{sound } Q \land 0 \leq a \land 0 \leq b \land 0 \leq c \right) \implies
\ a \ast t\ P\ s + b \ast t\ Q\ s \ominus c
\ leq t\ \left( \lambda s'. a \ast P\ s' + b \ast Q\ s' \ominus c \right) s) \]

**lemma** sublinear\[\text{intro}\] :
Figure 3.4: A graphical depiction of sub-additivity as convexity.

\[ Q = tP \cap uP \]

\[ Q(x) = Q(y) \]

\[ \frac{x+y}{2} \]

\[ \lambda s'. a \ast P s' + b \ast Q s' \ominus c \]

Sub-additivity, together with scaling (Section 3.2.2) gives the linear portion of sublinearity. Together, these two properties are equivalent to convexity, as Figure 3.4 illustrates by analogy.

Here \( P \) is an affine function (expectation) \( real \Rightarrow real \), restricted to some finite interval. In practice the state space (the left-hand type) is typically
discrete and multi-dimensional, but on the reals we have a convenient geometrical intuition. The lines $tP$ and $uP$ represent the effect of two healthy transformers (again affine). Neither monotonicity nor scaling are represented, but both are feasible: Both lines are bounded above by the greatest value of $P$.

The curve $Q$ is the pointwise minimum of $tP$ and $tQ$, written $tP \sqcap tQ$. This is, not coincidentally, the syntax for a binary nondeterministic choice in pGCL: The probability that some property is established by the choice between programs $a$ and $b$ cannot be guaranteed to be any higher than either the probability under $a$, or that under $b$.

The original curve, $P$, is trivially convex—it is linear. Also, both $t$ and $u$, and the operator $\sqcap$ preserve convexity. A probabilistic choice will also preserve it. The preservation of convexity is a property of sub-additive transformers that respect scaling. Note the form of the definition of convexity:

$$\forall x, y. \frac{Q(x) + Q(y)}{2} \leq Q\left(\frac{x + y}{2}\right)$$

Were we to replace $Q$ by some sub-additive transformer $v$, and $x$ and $y$ by expectations $R$ and $S$, the equivalent expression:

$$\frac{vR + vS}{2} \leq v\left(\frac{R + S}{2}\right)$$

Can be rewritten, using scaling, to:

$$\frac{1}{2}(vR + vS) \leq \frac{1}{2}v(R + S)$$

Which holds everywhere exactly when $v$ is sub-additive i.e.:

$$vR + vS \leq v(R + S)$$

**lemma sub-addI[intro]:**

$$\forall P, Q. \left[\text{sound } P; \text{ sound } Q\right] \implies tP s + tQ s \leq t(\lambda s'. P s' + Q s') s \implies \text{sub-add } t$$

(proof)

**lemma sub-addI2:**

$$\forall P, Q. \left[\text{sound } P; \text{ sound } Q\right] \implies \lambda s. tP s + tQ s \parallel t(\lambda s'. P s' + Q s) \implies \text{sub-add } t$$

(proof)

**lemma sub-addD[dest]:**

$$\forall P, Q. \left[\text{sub-add } t; \text{ sound } P; \text{ sound } Q\right] \implies tP s + tQ s \leq t(\lambda s'. P s' + Q s') s$$

(proof)
CHAPTER 3. SEMANTIC STRUCTURES

**Lemma** equiv-sub-add:
*fixes t::('s ⇒ real) ⇒ 's ⇒ real

 *assumes sat: sub-add t
   and ht: healthy t
   and sP: ∀x. sound (P x)
 *shows (∑y∈S. t (P y) x) ≤ t (∑y∈S. P y x)*

(Proof)

**Lemma** sub-add-guard-split:
*fixes t::'s:finite trans and P::'s expect and s::'s
 *assumes sat: sub-add t
   and ht: healthy t
   and sP: sound P
 *shows (∑y∈{s. G s}. P y * t «λz. z = y» s) +
   (∑y∈{s. ¬G s}. P y * t «λz. z = y» s) ≤ t P s*

(Proof)

**Sub-distributivity**

**Definition** sub-distrib ::
*(('s ⇒ real) ⇒ ('s ⇒ real)) ⇒ bool
 where
 sub-distrib t ↔ (∀ P s. sound P → t P s ⊕ 1 ≤ t (λs'. P s' ⊕ 1) s)*

**Lemma** sub-distribI[intro]:
*[[ ∀P s. sound P → t P s ⊕ 1 ≤ t (λs'. P s' ⊕ 1) s ]] → sub-distrib t*

(Proof)
3.2. EXPECTATION TRANSFORMERS

**Lemma** sub-distrib12:
\[
\{ \forall P. \text{sound } P \implies \lambda s. t \ P s \ominus 1 \vdash t (\lambda s'. P s' \ominus 1) \} \implies \text{sub-distrib } t
\]
(proof)

**Lemma** sub-distribD[dest]:
\[
\{ \text{sub-distrib } t; \text{sound } P \} \implies t P s \ominus 1 \leq t (\lambda s'. P s' \ominus 1) s
\]
(proof)

**Lemma** equiv-sub-distrib:

*fixes* \( t \colon (s \Rightarrow \text{real}) \Rightarrow (s' \Rightarrow \text{real}) \)

*assumes* eq: equiv-trans \( t u \)

*and* sd: sub-distrib \( t \)

*shows* sub-distrib \( u \)
(proof)

Sublinearity implies sub-distributivity:

**Lemma** sublinear-sub-distrib:

*fixes* \( t \colon (s \Rightarrow \text{real}) \Rightarrow (s' \Rightarrow \text{real}) \)

*assumes* slt: sublinear \( t \)

*shows* sub-distrib \( t \)
(proof)

Healthiness, sub-additivity and sub-distributivity imply sublinearity. This is how we usually show sublinearity.

**Lemma** sd-sa-sublinear:

*fixes* \( t \colon (s \Rightarrow \text{real}) \Rightarrow (s' \Rightarrow \text{real}) \)

*assumes* sdt: sub-distrib \( t \) and sat: sub-add \( t \) and ht: healthy \( t \)

*shows* sublinear \( t \)
(proof)

**Sub-conjunctivity**

**Definition**

\[ \text{sub-conj } \colon (s \Rightarrow \text{real}) \Rightarrow (s' \Rightarrow \text{real}) \Rightarrow \text{bool} \]

*where*

\[ \text{sub-conj } t \equiv \forall P Q. (\text{sound } P \land \text{sound } Q) \implies t P \&\& t Q \vdash t (P \&\& Q) \]

**Lemma** sub-conjI[intro]:
\[
\{ \forall P Q. [\text{sound } P; \text{sound } Q ] \implies t P \&\& t Q \vdash t (P \&\& Q) \} \implies \text{sub-conj } t
\]
(proof)

**Lemma** sub-conjD[dest]:
\[
\{ \text{sub-conj } t; \text{sound } P; \text{sound } Q \} \implies t P \&\& t Q \vdash t (P \&\& Q)
\]
(proof)

**Lemma** sub-conj-wp-twice:
fixes \( f :: 's \Rightarrow ('s \Rightarrow \text{real}) \Rightarrow ('s \Rightarrow \text{real}) \)
assumes all: \( \forall s. \text{sub-conj} (f s) \)
show sub-conj \( (\lambda P \ s. f P s) \)
\( \langle \text{proof}\rangle \)

Sublinearity implies sub-conjunctivity:

lemma sublinear-sub-conj:
fixes \( t :: ('s \Rightarrow \text{real}) \Rightarrow ('s \Rightarrow \text{real}) \)
assumes slt: \( \text{sublinear} t \)
shows sub-conj \( t \)
\( \langle \text{proof}\rangle \)

Sublinearity under equivalence

Sublinearity is preserved by equivalence.

lemma equiv-sublinear:
\[ \begin{array}{l}
\text{equiv-trans } t \ u; \text{sublinear } t \Rightarrow \text{sublinear } u
\end{array} \]
\( \langle \text{proof}\rangle \)

3.2.4 Determinism

Transformers which are both additive, and maximal among those that satisfy feasibility are deterministic, and will turn out to be maximal in the refinement order.

Additivity

Full additivity is not generally satisfied. It holds for (sub-)probabilistic transformers however.

definition additive :: \( ('a \Rightarrow \text{real}) \Rightarrow ('a \Rightarrow \text{real}) \Rightarrow \text{bool} \)
where
additive \( t \equiv \forall P Q. (\text{sound } P \land \text{sound } Q) \Rightarrow t (\lambda s. P s + Q s) = (\lambda s. t P s + t Q s) \)

lemma additiveD:
\[ \begin{array}{l}
\text{additive } t; \text{sound } P; \text{sound } Q \Rightarrow t (\lambda s. P s + Q s) = (\lambda s. t P s + t Q s)
\end{array} \]
\( \langle \text{proof}\rangle \)

lemma additiveI[intro]:
\[ \begin{array}{l}
\forall P Q s. \ [ \text{sound } P; \text{sound } Q ] \Rightarrow t (\lambda s. P s + Q s) = t P s + t Q s
\end{array} \]
\( \Rightarrow \)
\additive \( t \)
\( \langle \text{proof}\rangle \)

Additivity is strictly stronger than sub-additivity.

lemma additive-sub-add:
additive \( t \Rightarrow \text{sub-add } t \)
3.2. EXPECTATION TRANSFORMERS

The additivity property extends to finite summation.

**Lemma** `additive-sum`:

- **Fixes** `S: 's set`
- **Assumes** `additive t` and `healthy t` and `finite S` and `sPz`
- **Shows** `t (∑ y∈S. P y x) = (∑ y∈S. t (P y) x)`

An additive transformer (over a finite state space) is linear: it is simply the weighted sum of final expectation values, the weights being the probability of reaching a given final state. This is useful for reasoning using the forward, or “gambling game” interpretation.

**Lemma** `additive-delta-split`:

- **Fixes** `t: ('s::finite ⇒ real) ⇒ 's ⇒ real`
- **Assumes** `additive t` and `ht` and `sP`
- **Shows** `t P x = (∑ y∈UNIV. y * t «λ z. z = y» x)`

We can group the states in the linear form, to split on the value of a predicate (guard).

**Lemma** `additive-guard-split`:

- **Fixes** `t: ('s::finite ⇒ real) ⇒ 's ⇒ real`
- **Assumes** `additive t` and `ht` and `sP`
- **Shows** `t P x = (∑ y∈{s. G s}. P y * t «λ z. z = y» x) + (∑ y∈{s. ¬ G s}. P y * t «λ z. z = y» x)`

**Maximality**

**Definition** `maximal`:

- `maximal :: (('a ⇒ real) ⇒ 'a ⇒ real) ⇒ bool`
- **Where** `maximal t ≡ ∀ c. 0 ≤ c → t (λ-. c) = (λ-. c)`

**Lemma** `maximalI` [intro]:

- `∧ c. 0 ≤ c → t (λ-. c) = (λ-. c) → maximal t`

**Lemma** `maximalD` [dest]:

- `maximal t; 0 ≤ c → t (λ-. c) = (λ-. c)`
A transformer that is both additive and maximal is deterministic:

**definition** determ :: (('a ⇒ real) ⇒ 'a ⇒ real) ⇒ bool

**where**

determ t ≡ additive t ∧ maximal t

**lemma** determI[intro]:

\[
\begin{array}{l}
\text{additive } t;
\text{maximal } t \\
\end{array}
\implies \text{determ } t
\]

**proof**

**lemma** determ-additiveD[intro]:

determ t ⇒ additive t

**proof**

**lemma** determ-maximalD[intro]:

determ t ⇒ maximal t

**proof**

For a fully-deterministic transformer, a transformed standard expectation, and its transformed negation are complementary.

**lemma** determ-negate:

**assumes** determ: determ t

**shows** t «P» s + t «N» P s = 1

**proof**

### 3.2.5 Modular Reasoning

The emphasis of a mechanised logic is on automation, and letting the computer tackle the large, uninteresting problems. However, as terms generally grow exponentially in the size of a program, it is still essential to break up a proof and reason in a modular fashion.

The following rules allow proof decomposition, and later will be incorporated into a verification condition generator.

**lemma** entails-combine:

**assumes** wp1: P ⊢ t R

\[ \text{and} \ wp2: Q ⊢ t S \]

\[ \text{and} \ sc: \ sub-conj \ t \]

\[ \text{and} \ sR: \ sound \ R \]

\[ \text{and} \ sS: \ sound \ S \]

**shows** P & & Q ⊢ t (R & & S)

**proof**

These allow mismatched results to be composed

**lemma** entails-strengthen-post:

\[
\begin{array}{l}
[ \ P \vdash t \ Q; \ healthy \ t; \ sound \ R; \ Q \vdash R; \ sound \ Q ] \\
\end{array}
\implies P \vdash t \ R
\]

**proof**
3.2. EXPECTATION TRANSFORMERS

**Lemma entails-weaken-pre:**

\[ [ Q \vdash t \ R; \ P \vdash Q ] \implies P \vdash t \ R \]

(proof)

This rule is unique to pGCL. Use it to scale the post-expectation of a rule to ‘fit under’ the precondition you need to satisfy.

**Lemma entails-scale:**

assumes \( wp: P \vdash t \ Q \) and \( h: \text{healthy} \ t \)

and \( sQ: \text{sound} \ Q \) and \( \text{pos} : 0 \leq c \)

shows \((\lambda s. c * P \ s) \vdash t (\lambda s. c * Q \ s)\)

(proof)

3.2.6 Transforming Standard Expectations

Reasoning with standard expectations, those obtained by embedding a predicate, is often easier, as the analogues of many familiar boolean rules hold in modified form.

One may use a standard pre-expectation as an assumption:

**Lemma use-premise:**

assumes \( h: \text{healthy} \ t \) and \( wP: \bigwedge s. P \ s \implies 1 \leq t \ «Q» \ s \)

shows \( «P» \vdash t \ «Q» \)

(proof)

The other direction works too.

**Lemma fold-premise:**

assumes \( ht \): \text{healthy} \ t

and \( wp: «P» \vdash t \ «Q» \)

shows \( \forall s. P \ s \implies 1 \leq t \ «Q» \ s \)

(proof)

Predicate conjunction behaves as expected:

**Lemma conj-post:**

\[ [ P \vdash t \ «\lambda s. Q \ s \land R \ s»; \ \text{healthy} \ t ] \implies P \vdash t \ «Q» \]

(proof)

Similar to \[\text{healthy} \ ?t; \ \bigwedge s. \ ?P \ s \implies 1 \leq ?t \ «\ ?Q \ s]\implies « \ ?P \ » \vdash ?t \ «\ ?Q \ »\], but more general.

**Lemma entails-pconj-assumption:**

assumes \( f: \text{feasible} \ t \) and \( wP: \bigwedge s. P \ s \implies Q \ s \leq t \ R \ s \)

and \( uQ: \text{unitary} \ Q \) and \( uR: \text{unitary} \ R \)

shows \( «P» \land Q \vdash t \ R \)

(proof)

end
3.3 Induction

theory Induction
  imports Expectations Transformers
begin

3.3.1 The Lattice of Expectations

Defining recursive (or iterative) programs requires us to reason about fixed points on the semantic objects, in this case expectations. The complication here, compared to the standard Knaster-Tarski theorem (for example, as shown in HOL.Inductive), is that we do not have a complete lattice.

Finding a lower bound is easy (it’s $\lambda$. 0::'b), but as we do not insist on any global bound on expectations (and work directly in HOL’s real type, rather than extending it with a point at infinity), there is no top element.

We solve the problem by defining the least (greatest) fixed point, restricted to an internally-bounded set, allowing us to substitute this bound for the top element. This works as long as the set contains at least one fixed point, which appears as an extra assumption in all the theorems.

This also works semantically, thanks to the definition of healthiness. Given a healthy transformer parameterised by some sound expectation: $t$. Imagine that we wish to find the least fixed point of $t P$. In practice, $t$ is generally doubly healthy, that is $\forall P. \text{sound } P \rightarrow \text{healthy } (t P)$ and $\forall Q. \text{sound } Q \rightarrow \text{healthy } (\lambda P. t P Q)$. Thus by feasibility, $t P Q$ must be bounded by $\text{bound-of } P$. Thus, as by definition $x \leq t P x$ for any fixed point, all must lie in the set of sound expectations bounded above by $\lambda-. \text{bound-of } P$.

definition Inf-exp :: 's expect set ⇒ 's expect
where Inf-exp S = (λs. Inf {f s | f ∈ S})

lemma Inf-exp-lower:
[ P ∈ S; ∀P∈S. nneg P ] ⇒ Inf-exp S ≤ P
⟨proof⟩

lemma Inf-exp-greatest:
[ S ≠ {}; ∀P∈S. Q ≤ P ] ⇒ Q ≤ Inf-exp S
⟨proof⟩

definition Sup-exp :: 's expect set ⇒ 's expect
where Sup-exp S = (if S = {} then $\lambda$s. 0 else (λs. Sup {f s | f ∈ S}))

lemma Sup-exp-upper:
[ P ∈ S; ∀P∈S. bounded-by b P ] ⇒ P ≤ Sup-exp S
⟨proof⟩

lemma Sup-exp-least:
[ ∀P∈S. P ≤ Q; nneg Q ] ⇒ Sup-exp S ≤ Q
3.3. INDUCTION

-proof-

**lemma** Sup-exp-sound:
- **assumes** sS: \( \forall P. P \in S \implies \text{sound } P \)
- and bS: \( \forall P. P \in S \implies \text{bounded-by } b P \)
- **shows** sound \((\text{Sup-exp } S)\)

-proof-

**definition** lfp-exp :: 's trans ⇒ 's expect
where lfp-exp \( t = \text{Inf-exp } \{ P. \text{sound } P \land t P \leq P \} \)

**lemma** lfp-exp-lowerbound:
- \([\ [ t P \leq P; \text{sound } P ] ] \implies \text{lfp-exp } t \leq P\)

-proof-

**lemma** lfp-exp-greatest:
- \([\ [ \forall P. [ [ t P \leq P; \text{sound } P ] ] \implies Q \leq P; \text{sound } Q; t R \vdash R; \text{sound } R ] ] \implies Q \leq \text{lfp-exp } t\)

-proof-

**lemma** feasible-lfp-exp-sound:
- feasible \( t \implies \text{sound } (\text{lfp-exp } t)\)

-proof-

**lemma** lfp-exp-bound:
- \((\forall P. \text{unitary } P \implies \text{unitary } (t P)) \implies \text{bounded-by } t (\text{lfp-exp } t)\)

-proof-

  \end{array} \right] \implies t \ P \vdash t \ Q) \rightarrow gfp-exp \ t = t \ (gfp-exp \ t)
  \]
  \( \langle \text{proof} \rangle \)
3.3. INDUCTION

3.3.2 The Lattice of Transformers

In addition to fixed points on expectations, we also need to reason about fixed points on expectation transformers. The interpretation of a recursive program in pGCL is as a fixed point of a function from transformers to transformers. In contrast to the case of expectations, healthy transformers do form a complete lattice, where the bottom element is $\lambda\cdot -\cdot 0::\cdot c$, and the top element is the greatest allowed by feasibility: $\lambda\cdot P::\cdot bound-of P$.

definition Inf-trans :: 's trans set $\Rightarrow$ 's trans
where Inf-trans $S = (\lambda P. \ Inf-exp \{ t P \mid t \in S \})$

lemma Inf-trans-lower:
\[ \{ t \in S; \forall u \in S. \forall P. \ sound P \rightarrow sound (u P) \} \Rightarrow le-trans (\ Inf-trans S ) t \]

lemma Inf-trans-greatest:
\[ \{ S \neq \{\}; \forall t \in S. \forall P. \ le-trans u t \} \Rightarrow le-trans u (\ Inf-trans S ) \]

definition Sup-trans :: 's trans set $\Rightarrow$ 's trans
where Sup-trans $S = (\lambda P. \ Sup-exp \{ t P \mid t \in S \})$

lemma Sup-trans-upper:
\[ \{ t \in S; \forall u \in S. \forall P. \ unitary P \rightarrow unitary (u P) \} \Rightarrow le-utrans t (\ Sup-trans S ) \]

lemma Sup-trans-upper2:
\[ \{ t \in S; \forall u \in S. \forall P. \ (\ nneg P \land bounded-by b P ) \rightarrow (\ nneg (u P) \land bounded-by b (u P)) \};
\[ nneg P; \ bounded-by b P \} \Rightarrow t P \vdash Sup-trans S P \]

lemma Sup-trans-least:
\[ \{ \forall t \in S. \ le-utrans t u; \forall P. \ unitary P \Rightarrow unitary (u P) \} \Rightarrow le-utrans (\ Sup-trans S ) u \]

lemma Sup-trans-least2:
\[ \{ \forall t \in S. \forall P. \ nneg P \rightarrow bounded-by b P \rightarrow t P \not\models u P ;
\[ \forall u \in S. \forall P. \ (\ nneg P \land bounded-by b P ) \rightarrow (\ nneg (u P) \land bounded-by b (u P)) \};
\[ nneg P; \ bounded-by b P ; \forall P. \ [ \ nneg P; \ bounded-by b P \} \Rightarrow nneg (u P) \ [ \Rightarrow Sup-trans S P \vdash u P \]

lemma feasible-Sup-trans:
fixes $S$::’s trans set
assumes $fS$: $\forall t \in S$. feasible $t$
shows feasible $(\text{Sup-trans } S)$
⟨proof⟩

**definition** $\text{lfp-trans} :: (’s trans \Rightarrow ’s trans) \Rightarrow ’s trans$

where $\text{lfp-trans } T = \text{Inf-trans } \{(t. (\forall P. \text{sound } P \implies \text{sound } (t P))) \land \text{le-trans } (T t) t\}$

**lemma** $\text{lfp-trans-lowerbound}$:

$\begin{align*}
\text{le-trans } (T t) t; \bigwedge P. \text{sound } P \implies \text{sound } (t P) \implies \text{le-trans } (\text{lfp-trans } T) t
\end{align*}$

⟨proof⟩

**lemma** $\text{lfp-trans-greatest}$:

$\begin{align*}
\bigwedge \bigwedge P. \text{sound } P \implies \text{sound } (t P) \implies \text{le-trans } u t; \\
\bigwedge P. \text{sound } P \implies \text{sound } (v P); \text{le-trans } (T v) v \implies \text{le-trans } u (\text{lfp-trans } T)
\end{align*}$

⟨proof⟩

**lemma** $\text{lfp-trans-sound}$:

fixes $P Q$::’s expect
assumes $sP$: $\text{sound } P$
and $fv$: $\text{le-trans } (T v) v$
and $sv$: $\bigwedge P. \text{sound } P \implies \text{sound } (v P)$
shows $\text{sound } (\text{lfp-trans } T P)$
⟨proof⟩

**lemma** $\text{lfp-trans-unitary}$:

fixes $P Q$::’s expect
assumes $uP$: $\text{unitary } P$
and $fv$: $\text{le-trans } (T v) v$
and $sv$: $\bigwedge P. \text{sound } P \implies \text{sound } (v P)$
and $fT$: $\text{le-trans } (T (\lambda P s. \text{bound-of } P)) (\lambda P s. \text{bound-of } P)$
shows $\text{unitary } (\text{lfp-trans } T P)$
⟨proof⟩

**lemma** $\text{lfp-trans-lemma2}$:

fixes $v$::’s trans
assumes $\text{mono}$: $\bigwedge t u. [\text{le-trans } t u; \bigwedge P. \text{sound } P \implies \text{sound } (t P); \\
\bigwedge P. \text{sound } P \implies \text{sound } (u P)] \implies \text{le-trans } (T t) (T u)$
and $nT$: $\bigwedge t P. [\bigwedge Q. \text{sound } Q \implies \text{sound } (t Q); \text{sound } P] \implies \text{sound } (T t P)$
and $fv$: $\text{le-trans } (T v) v$
and $sv$: $\bigwedge P. \text{sound } P \implies \text{sound } (v P)$
shows $\text{le-trans } (T (\text{lfp-trans } T)) (\text{lfp-trans } T)$
⟨proof⟩

**lemma** $\text{lfp-trans-lemma3}$:

fixes $v$::’s trans
assumes \( \text{mono} \): 
\[
\forall t, u. \quad \text{le-trans } t \equiv u \quad \land \quad \forall P. \quad \text{sound } P \implies \text{sound } (t P) \quad \land \quad \forall P. \quad \text{sound } P \implies \text{sound } (u P) \quad \implies \quad \text{le-trans } (T t) (T u) \]

and \( sT \):
\[
\forall t. \quad [\forall Q. \quad \text{sound } Q \implies \text{sound } (t Q); \quad \text{sound } P] \implies \text{sound } (t P) \quad \land \quad \forall P. \quad \text{sound } P \implies \text{sound } (u P) \quad \implies \quad \text{le-trans } (T t) (T u) \]

and \( f v \):
\[
\text{le-trans } (T v) v \quad \land \quad \forall P. \quad \text{sound } P \implies \text{sound } (v P) \]

shows \( \text{le-trans } (\text{lfp-trans } T) (T (\text{lfp-trans } T)) \)

\( \langle \text{proof} \rangle \)

\( \text{lemma } \text{lfp-trans-unfold}: \)

\( \langle \text{proof} \rangle \)

end
Chapter 4

The pGCL Language

4.1 A Shallow Embedding of pGCL in HOL

theory Embedding imports Misc Induction begin

4.1.1 Core Primitives and Syntax

A pGCL program is embedded directly as its strict or liberal transformer. This is achieved with an additional parameter, specifying which semantics should be obeyed.

```markdown
type-synonym 's prog = bool ⇒ ('s ⇒ real) ⇒ ('s ⇒ real)

Abort either always fails, λP s. 0::'c, or always succeeds, λP s. 1::'c.

definition Abort :: 's prog
  where Abort ≡ λab P s. if ab then 0 else 1

Skip does nothing at all.

definition Skip :: 's prog
  where Skip ≡ λab P s. P

Apply lifts a state transformer into the space of programs.

definition Apply :: ('s ⇒ 's) ⇒ 's prog
  where Apply f ≡ λab P s. f s

Seq is sequential composition.

definition Seq :: 's prog ⇒ 's prog ⇒ 's prog
  (infixl ;; 59)
  where Seq a b ≡ (λab. a ab o b ab)

PC is probabilistic choice between programs.

definition PC :: 's prog ⇒ ('s ⇒ real) ⇒ 's prog ⇒ 's prog
  (- ⊕ - [58,57,57] 57)
  where PC a P b ≡ λab Q s. P s * a ab Q s + (1 − P s) * b ab Q s
```
**CHAPTER 4. THE PGCL LANGUAGE**

*DC* is *demonic* choice between programs.

**definition** DC :: 's prog ⇒ 's prog ⇒ 's prog (- ⋃ - [58,57] 57)

**where** DC a b ≡ λab Q s. min (a ab Q s) (b ab Q s)

*AC* is *angelic* choice between programs.

**definition** AC :: 's prog ⇒ 's prog ⇒ 's prog (- ⋂ - [58,57] 57)

**where** AC a b ≡ λab Q s. max (a ab Q s) (b ab Q s)

*Embed* allows any expectation transformer to be treated syntactically as a program, by ignoring the failure flag.

**definition** Embed :: 's trans ⇒ 's prog

**where** Embed t = (λab. t)

*Mu* is the recursive primitive, and is either then least or greatest fixed point.

**definition** Mu :: ('s prog ⇒ 's prog) ⇒ 's prog

**where** Mu (T) ≡ (λab. if ab then lfp-trans (λt. T (Embed t) ab) else gfp-trans (λt. T (Embed t) ab))

**repeat** expresses finite repetition

**primrec**

repeat :: nat ⇒ 'a prog ⇒ 'a prog

**where**

repeat 0 p = Skip |
repeat (Suc n) p = p ;; repeat n p

*SetDC* is demonic choice between a set of alternatives, which may depend on the state.

**definition** SetDC :: ('a ⇒ 's prog) ⇒ ('s ⇒ 'a set) ⇒ 's prog

**where** SetDC f S ≡ λab P s. Inf ((λa. f a ab P s)' S s)

**syntax** -SetDC :: pttrn => ('s => 'a set) => 's prog => 's prog

**translations** ⋃x ∈ S. p == CONST SetDC (\%x. p) S

The above syntax allows us to write ⋃x ∈ S. Apply f

*SetPC* is *probabilistic* choice from a set. Note that this is only meaningful for distributions of finite support.

**definition** SetPC :: ('a ⇒ 's prog) ⇒ ('s ⇒ 'a ⇒ real) ⇒ 's prog

**where** SetPC f p ≡ λab P s. ∑a ∈ supp (p s). p s a * f a ab P s

*Bind* allows us to name an expression in the current state, and re-use it later.

**definition**

Bind :: ('s ⇒ 'a) ⇒ ('a ⇒ 's prog) ⇒ 's prog
where

\[ \text{Bind} \ g \ f \ a \ b \equiv \lambda P \ s. \ \text{let} \ a = g \ s \ \text{in} \ f \ a \ a \ b \ P \ s \]

This gives us something like let syntax

\[ \text{syntax} \ -\text{Bind} :: \text{pttrn} = \Rightarrow (\begin{array}{r} \text{\'} s \Rightarrow \text{\'} a \Rightarrow \text{\'} s \ prog \Rightarrow \text{\'} s \ prog \\
\text{\text{- is - in - \[55,55,55\]55}
\end{array}) \]

\[ \text{translations} \ x \ is \ f \ in \ a \Rightarrow \text{CONST} \ \text{Bind} f (%x. \ a) \]

\[ \text{definition} \ \text{flip} :: (\begin{array}{r} \text{\'} a \Rightarrow \text{\'} b \Rightarrow \text{\'} c \\
\text{\text{- is - in - \[55,55,55\]55}
\end{array}) \Rightarrow (\begin{array}{r} \text{\'} b \Rightarrow \text{\'} a \Rightarrow \text{\'} c \\
\text{\text{- is - in - \[55,55,55\]55}
\end{array}) \]

\[ \text{where} \ \text{[simp]} : \text{flip} \ f = (\lambda b \ a. \ f \ a \ b) \]

The following pair of translations introduce let-style syntax for \( \text{SetPC} \) and \( \text{SetDC} \), respectively.

\[ \text{syntax} \ -\text{PBind} :: \text{pttrn} = \Rightarrow (\begin{array}{r} \text{\'} s \Rightarrow \text{\'} a \Rightarrow \text{\'} real \\
\text{\text{- is - in - \[55,55,55\]55}
\end{array}) \Rightarrow \text{\'} s \ prog \Rightarrow \text{\'} s \ prog \]

\[ \text{translations} \ \text{bind} \ x \ at \ p \ in \ a \Rightarrow \text{CONST} \ \text{SetPC} (%x. \ a) \ (\text{CONST} \ \text{flip} (%x. \ p)) \]

\[ \text{syntax} \ -\text{DBind} :: \text{pttrn} = \Rightarrow (\begin{array}{r} \text{\'} s \Rightarrow \text{\'} a \ \text{set} \\
\text{\text{- is - in - \[55,55,55\]55}
\end{array}) \Rightarrow \text{\'} s \ prog \Rightarrow \text{\'} s \ prog \]

\[ \text{translations} \ \text{bind} \ x \ from \ S \ in \ a \Rightarrow \text{CONST} \ \text{SetDC} (%x. \ a) \ S \]

The following syntax translations are for convenience when using a record as the state type.

\[ \text{syntax} \ -\text{assign} :: \text{ident} = \Rightarrow (\begin{array}{r} \text{\'} a \Rightarrow \text{\'} real \\
\text{\text{- is - in - \[1000,900\]900}
\end{array}) \Rightarrow \text{\'} s \ prog \Rightarrow \text{\'} s \ prog \]

\[ \text{⟨ML⟩} \]

\[ \text{syntax} \ -\text{SetPC} :: \text{ident} = \Rightarrow (\begin{array}{r} \text{\'} a \Rightarrow \text{\'} real \\
\text{\text{- is - in - \[66,66\]66}
\end{array}) \Rightarrow \text{\'} s \ prog \Rightarrow \text{\'} s \ prog \]

\[ \text{⟨ML⟩} \]

\[ \text{syntax} \ -\text{set-dc} :: \text{ident} = \Rightarrow (\begin{array}{r} \text{\'} a \ \text{set} \\
\text{\text{- is - in - \[66,66\]66}
\end{array}) \Rightarrow \text{\'} s \ prog \Rightarrow \text{\'} s \ prog \]

\[ \text{⟨ML⟩} \]

These definitions instantiate the embedding as either weakest precondition (True) or weakest liberal precondition (False).

\[ \text{syntax} \ -\text{set-dc-UNIV} :: \text{ident} = \Rightarrow \text{\'} s \ prog \Rightarrow \text{\'} s \ prog \]

\[ \text{⟨ML⟩} \]

\[ \text{translations} \ \text{set-dc-UNIV} \ x \Rightarrow \text{-set-dc} \ x \ (%x. \ \text{CONST} \ \text{UNIV}) \]

\[ \text{definition} \ \text{wp} :: \text{\'} s \ prog \Rightarrow \text{\'} s \ trans \]

\[ \text{where} \ \text{wp} \ \text{pr} \equiv \text{pr} \ \text{True} \]
definition

\[ wlp :: \text{'s prog} \Rightarrow \text{'s trans} \]

where

\[ wlp \ pr \equiv pr \ False \]

If-Then-Else as a degenerate probabilistic choice.

abbreviation (input)

\[ \text{if-then-else} :: [\text{'s \Rightarrow \text{bool}, \text{'s prog}, \text{'s prog}] \Rightarrow \text{'s prog} \]

\[ (\text{If - Then - Else - 58}) \]

where

\[ \text{If } P \text{ Then } a \text{ Else } b \equiv a \ _{\times \ P} \oplus b \]

Syntax for loops

abbreviation

\[ \text{do-while :: [\text{'s \Rightarrow \text{bool, \text{'s prog}] \Rightarrow \text{'s prog} \]

\[ (\text{do - 

\text{4 -} // (4 -) // od} \]

where

\[ \text{do-while } P \ a \equiv \mu \ x. \ \text{If } P \text{ Then } a \odot x \text{ Else Skip} \]

  and f::'a ⇒ 's prog
  assumes healthy: ∀a s. a ∈ supp (p s) ⇒ nearly-healthy (wlp (f a))
  and sound: ∀s. sound (p s)
  and sub-dist: ∀s. (∑a∈supp (p s). p s a) ≤ 1
  shows nearly-healthy (wlp (SetPC f p)) (is nearly-healthy 𝖎)
⟨proof⟩

lemma healthy-wp-Apply:
  healthy (wp (Apply f))
⟨proof⟩

lemma nearly-healthy-wlp-Apply:
  nearly-healthy (wlp (Apply f))
⟨proof⟩

lemma healthy-wp-Bind:
  fixes f::'s ⇒ 'a
  assumes hsub: ∀s. healthy (wp (p (f s)))
  shows healthy (wp (Bind f p))
⟨proof⟩

lemma nearly-healthy-wlp-Bind:
  fixes f::'s ⇒ 'a
  assumes hsub: ∀s. nearly-healthy (wlp (p (f s)))
  shows nearly-healthy (wlp (Bind f p))
⟨proof⟩

4.2.2 Healthiness for Loops

lemma wp-loop-step-mono:
  fixes t w::'s trans
assumes hb: healthy (wp body)
  and le: le-trans t u
  and ht: \( \forall P. \text{sound } P \implies \text{sound } (t P) \)
  and hu: \( \forall P. \text{sound } P \implies \text{sound } (u P) \)
shows le-trans (wp (body ;; Embed t « G » ⊕ Skip))
  (wp (body ;; Embed u « G » ⊕ Skip))

\langle proof \rangle

lemma wlp-loop-step-mono:
  fixes t u:′s trans
  assumes mb: nearly-healthy (wlp body)
  and le: le-trans t u
  and ht: \( \forall P. \text{unitary } P \implies \text{unitary } (t P) \)
  and hu: \( \forall P. \text{unitary } P \implies \text{unitary } (u P) \)
shows le-trans (wlp (body ;; Embed t « G » ⊕ Skip))
  (wlp (body ;; Embed u « G » ⊕ Skip))
\langle proof \rangle

For each sound expectation, we have a pre fixed point of the loop body. This
lets us use the relevant fixed-point lemmas.

lemma lfp-loop-fp:
  assumes hb: healthy (wp body)
  and sP: sound P
shows \( \lambda s. « G » s * wp body (\lambda s. \text{bound-of } P) s + « N G » s * P s \triangleright \lambda s. \text{bound-of } P \)
\langle proof \rangle

lemma lfp-loop-greatest:
  fixes P:′s expect
  assumes lb: \( \forall R. \lambda s. « G » s * wp body R s + « N G » s * P s \triangleright R \implies \text{sound } R \)
  and hb: healthy (wp body)
  and sP: sound P
  and sQ: sound Q
shows Q \triangleright lfp-exp (\lambda Q s. « G » s * wp body Q s + « N G » s * P s)
\langle proof \rangle

lemma lfp-loop-sound:
  fixes P:′s expect
  assumes hb: healthy (wp body)
  and sP: sound P
shows sound (lfp-exp (\lambda Q s. « G » s * wp body Q s + « N G » s * P s))
\langle proof \rangle

lemma wlp-loop-step-unitary:
  fixes t u:′s trans
  assumes hb: nearly-healthy (wlp body)
  and ht: \( \forall P. \text{unitary } P \implies \text{unitary } (t P) \)
  and uP: unitary P
4.2. HEALTHINESS

shows unitary (wp (body ;; Embed t « G + Skip) P)
⟨proof⟩

lemma wp-loop-step-sound:
  fixes t u:′s trans
  assumes hb: healthy (wp body)
     and ht: ∀P. sound P → sound (t P)
     and sP: sound P
  shows sound (wp (body ;; Embed t « G + Skip) P)
⟨proof⟩

This gives the equivalence with the alternative definition for loops[McIver and Morgan, 2004, §7, p. 198, footnote 23].

lemma wlp-Loop1:
  fixes body :: ′s prog
  assumes unitary: unitary P
     and healthy: nearly-healthy (wp body)
  shows wlp (do G → body od) P =
     gfp-exp (λQ s. «G» s * wlp body Q s + «N G» s * P s)
     (is ?X = gfp-exp (?Y P))
⟨proof⟩

lemma wp-loop-sound:
  assumes sP: sound P
     and hb: healthy (wp body)
  shows sound (wp do G → body od P)
⟨proof⟩

Likewise, we can rewrite strict loops.

lemma wp-Loop1:
  fixes body :: ′s prog
  assumes sP: sound P
     and healthy: healthy (wp body)
  shows wp (do G → body od) P =
     lfp-exp (λQ s. «G» s * wp body Q s + «N G» s * P s)
     (is ?X = lfp-exp (?Y P))
⟨proof⟩

lemma nearly-healthy-wlp-loop:
  fixes body::′s prog
  assumes hb: nearly-healthy (wp body)
  shows nearly-healthy (wp (do G → body od))
⟨proof⟩

We show healthiness by appealing to the properties of expectation fixed points, applied to the alternative loop definition.

lemma healthy-wp-loop:
  fixes body::′s prog
assumes $hb$: healthy (wp body)
shows healthy (wp (do $G \rightarrow$ body od))
(proof)

Use 'simp add:healthy_intros' or 'blast intro:healthy_intros' as appropriate

to discharge healthiness side-conditions for primitive programs automatically.

lemmas healthy-intros =
healthy-wp-Abort nearly-healthy-wlp-Abort healthy-wp-Skip nearly-healthy-wlp-Skip

healthy-wp-SetDC nearly-healthy-wlp-SetDC healthy-wp-SetPC nearly-healthy-wlp-SetPC
healthy-wp-Bind nearly-healthy-wlp-Bind healthy-wp-repeat nearly-healthy-wlp-repeat
healthy-wp-loop nearly-healthy-wlp-loop

end

4.3 Continuity

theory Continuity imports Healthiness begin

We rely on one additional healthiness property, continuity, which is shown
here separately, as its proof relies, in general, on healthiness. It is only
relevant when a program appears in an inductive context i.e. inside a loop.

A continuous transformer preserves limits (or the suprema of ascending
chains).

definition bd-cts :: 's trans ⇒ bool
where bd-cts t = (∀ M. (∀ i. M i ⊢ M (Suc i)) ∧ sound (M i) →
(∃ b. ∀ i. bounded-by b (M i)) →
t (Sup-exp (range M)) = Sup-exp (range (t o M)))

lemma bd-ctsD:
[ bd-cts t; (∀ i. M i ⊢ M (Suc i)); (∀ i. sound (M i)); (∀ i. bounded-by b (M i)) ] →
t (Sup-exp (range M)) = Sup-exp (range (t o M))
(proof)

lemma bd-ctsI:
(∀ b M. (∃ i. M i ⊢ M (Suc i)) → (∀ i. sound (M i)) → (∀ i. bounded-by b (M i)) →
t (Sup-exp (range M)) = Sup-exp (range (t o M))) → bd-cts t
(proof)

A generalised property for transformers of transformers.

definition bd-cts-tr :: ('s trans ⇒ 's trans) ⇒ bool
where bd-cts-tr T = (∀ M. (∃ i. le-trans (M i) (M (Suc i)) ∧ feasible (M i)) →
4.3. CONTINUITY

\[ \text{equiv-trans} (T (\text{Sup-trans} (M \cdot \text{UNIV}))) (\text{Sup-trans} ((T \circ M) \cdot \text{UNIV})) \]

**Lemma bd-cts-trD:**

\[ [\text{bd-cts-tr} T; \bigwedge i. \text{le-trans} (M i) (M (\text{Suc} i)); \bigwedge i. \text{feasible} (M i)] \implies \text{equiv-trans} (T (\text{Sup-trans} (M \cdot \text{UNIV}))) (\text{Sup-trans} ((T \circ M) \cdot \text{UNIV})) \]

(\text{proof})

**Lemma bd-cts-trI:**

\[ (\bigwedge M. (\bigwedge i. \text{le-trans} (M i) (M (\text{Suc} i))) \implies (\bigwedge i. \text{feasible} (M i)) \implies \text{equiv-trans} (T (\text{Sup-trans} (M \cdot \text{UNIV}))) (\text{Sup-trans} ((T \circ M) \cdot \text{UNIV}))) \]

\[ \implies \text{bd-cts-tr} T \]

(\text{proof})

4.3.1 Continuity of Primitives

**Lemma cts-wp-Abort:**

\[ \text{bd-cts} (\text{wp} (\text{Abort} :: \text{'s prog})) \]

(\text{proof})

**Lemma cts-wp-Skip:**

\[ \text{bd-cts} (\text{wp Skip}) \]

(\text{proof})

**Lemma cts-wp-Apply:**

\[ \text{bd-cts} (\text{wp} (\text{Apply} f)) \]

(\text{proof})

**Lemma cts-wp-Bind:**

\[ \text{fixes} a :: \text{'a} \Rightarrow \text{'s prog} \]

\[ \text{assumes ca:} \bigwedge s. \text{bd-cts} (\text{wp} (a (f s))) \]

\[ \text{shows} \text{bd-cts} (\text{wp} (\text{Bind} f a)) \]

(\text{proof})

The first nontrivial proof. We transform the suprema into limits, and appeal to the continuity of the underlying operation (here infimum). This is typical of the remainder of the nonrecursive elements.

**Lemma cts-wp-DC:**

\[ \text{fixes} a,b :: \text{'s prog} \]

\[ \text{assumes ca:} \text{bd-cts} (\text{wp} a) \]

\[ \text{and} \ cb: \text{bd-cts} (\text{wp} b) \]

\[ \text{and} \ ha: \text{healthy} (\text{wp} a) \]

\[ \text{and} \ hb: \text{healthy} (\text{wp} b) \]

\[ \text{shows} \text{bd-cts} (\text{wp} (a \sqcap b)) \]

(\text{proof})

**Lemma cts-wp-Seq:**

\[ \text{fixes} a,b :: \text{'s prog} \]

\[ \text{assumes ca:} \text{bd-cts} (\text{wp} a) \]
\[\begin{align*}
  \text{and } cb & : \text{bd-cts } (wp b) \\
  \text{and } hb & : \text{healthy } (wp b) \\
  \text{shows } \text{bd-cts } (wp (a ;; b))
\end{align*}\]

\[\langle \text{proof} \rangle\]

\textbf{Lemma cts-wp-PC:}
\begin{align*}
  \text{fixes } a \text{ b::'s prog} \\
  \text{assumes } ca & : \text{bd-cts } (wp a) \\
  \text{and } cb & : \text{bd-cts } (wp b) \\
  \text{and } ha & : \text{healthy } (wp a) \\
  \text{and } hb & : \text{healthy } (wp b) \\
  \text{and } up & : \text{unitary } p \\
  \text{shows } \text{bd-cts } (wp (PC a p b))
\end{align*}

\[\langle \text{proof} \rangle\]

Both set-based choice operators are only continuous for finite sets (probabilistic choice \textit{can} be extended infinitely, but we have not done so). The proofs for both are inductive, and rely on the above results on binary operators.

\textbf{Lemma SetPC-Bind:}
\begin{align*}
  \text{SetPC } a \text{ p } = \text{Bind } p (\lambda p. \text{SetPC } a (\lambda -. p))
\end{align*}

\[\langle \text{proof} \rangle\]

\textbf{Lemma SetPC-remove:}
\begin{align*}
  \text{assumes } nz & : p x \neq 0 \text{ and n1: } p x \neq 1 \\
  \text{and } fsupp & : \text{finite } (\text{supp } p) \\
  \text{shows } \text{SetPC } a (\lambda -. p) = \text{PC } (a x) (\lambda -. p x) (\text{SetPC } a (\lambda -. \text{dist-remove } p x))
\end{align*}

\[\langle \text{proof} \rangle\]

\textbf{Lemma cts-bot:}
\begin{align*}
  \text{bd-cts } (\lambda (P::'s \text{ expect}) (s::'s). 0::\text{real})
\end{align*}

\[\langle \text{proof} \rangle\]

\textbf{Lemma wp-SetPC-nil:}
\begin{align*}
  \text{wp } (\text{SetPC } a (\lambda s a 0)) = (\lambda P s. 0)
\end{align*}

\[\langle \text{proof} \rangle\]

\textbf{Lemma SetPC-sgl:}
\begin{align*}
  \text{supp } p = \{x\} \implies \text{SetPC } a (\lambda -. p) = (\lambda ab P s. p x * a x ab P s)
\end{align*}

\[\langle \text{proof} \rangle\]

\textbf{Lemma bd-cts-scale:}
\begin{align*}
  \text{fixes } a::'s \text{ trans} \\
  \text{assumes } ca & : \text{bd-cts } a \\
  \text{and } ha & : \text{healthy } a \\
  \text{and } nnc & : 0 \leq c \\
  \text{shows } \text{bd-cts } (\lambda P s. c * a P s)
\end{align*}

\[\langle \text{proof} \rangle\]
4.3. CONTINUITY

lemma cts-wp-SetPC-const:
  fixes $\alpha :: s \Rightarrow s$ prog
  assumes $\alpha a :: \bigwedge x. x \in (supp p) \Rightarrow \text{bd-cts} (wp (a x))$
  and $\alpha ha :: \bigwedge x. x \in (supp p) \Rightarrow \text{healthy} (wp (a x))$
  and $\alpha up :: \text{unitary} p$
  and $\alpha sump :: \text{sum} p (supp p) \leq 1$
  and $\alpha fsupp :: \text{finite} (supp p)$
  shows $\text{bd-cts} (wp (\text{SetPC} a (\lambda-. p)))$
⟨proof⟩

lemma cts-wp-SetPC:
  fixes $\alpha :: s \Rightarrow s$ prog
  assumes $\alpha ca :: \bigwedge x. x \in (supp (p s)) \Rightarrow \text{bd-cts} (wp (a x))$
  and $\alpha ha :: \bigwedge x. x \in (supp (p s)) \Rightarrow \text{healthy} (wp (a x))$
  and $\alpha up :: \text{unitary} (p s)$
  and $\alpha sump :: \text{sum} (p s) (supp (p s)) \leq 1$
  and $\alpha fsupp :: \text{finite} (supp (p s))$
  shows $\text{bd-cts} (wp (\text{SetPC} a p))$
⟨proof⟩

lemma wp-SetDC-Bind:
$\text{SetDC} a S = \text{Bind} S (\lambda S. \text{SetDC} a (\lambda-. S))$
⟨proof⟩

lemma SetDC-finite-insert:
  assumes $\beta S :: \text{finite} S$
  and $\beta neS :: S \neq \{\}$
  shows $\text{SetDC} a (\lambda-. \text{insert} x S) = a x \bigcap \text{SetDC} a (\lambda-. S)$
⟨proof⟩

lemma SetDC-singleton:
$\text{SetDC} a (\lambda-. \{x\}) = a x$
⟨proof⟩

lemma cts-wp-SetDC-const:
  fixes $\alpha :: s \Rightarrow s$ prog
  assumes $\alpha ca :: \bigwedge x. x \in S \Rightarrow \text{bd-cts} (wp (a x))$
  and $\alpha ha :: \bigwedge x. x \in S \Rightarrow \text{healthy} (wp (a x))$
  and $\alpha fS :: \text{finite} S$
  and $\alpha neS :: S \neq \{\}$
  shows $\text{bd-cts} (wp (\text{SetDC} a (\lambda-. S)))$
⟨proof⟩

lemma cts-wp-SetDC:
  fixes $\alpha :: s \Rightarrow s$ prog
  assumes $\alpha ca :: \bigwedge x. x \in S s \Rightarrow \text{bd-cts} (wp (a x))$
  and $\alpha ha :: \bigwedge x. x \in S s \Rightarrow \text{healthy} (wp (a x))$
  and $\alpha fS :: \text{finite} (S s)$
  and $\alpha neS :: S s \neq \{\}$
shows \( bd-cts \ (wp \ (SetDC \ a \ S)) \)
\( \langle \text{proof} \rangle \)

**lemma cts-wp-repeat:**
\( bd-cts \ (wp \ a) \implies healthy \ (wp \ a) \implies bd-cts \ (wp \ \text{repeat} \ n \ a) \)
\( \langle \text{proof} \rangle \)

**lemma cts-wp-Embed:**
\( bd-cts \ t \implies bd-cts \ (wp \ (Embed \ t)) \)
\( \langle \text{proof} \rangle \)

### 4.3.2 Continuity of a Single Loop Step

A single loop iteration is continuous, in the more general sense defined above for transformer transformers.

**lemma cts-wp-loopstep:**
\[ \text{fixes } body ::'s \ prog \]
\[ \text{assumes } hb : healthy \ (wp \ body) \]
\[ \text{and } cb : bd-cts \ (wp \ body) \]
\[ \text{shows } bd-cts-tr \ (\lambda x. \ wp \ (body \ ;; \ Embed x \ «G» \.skip) \) \ (is \ bd-cts-tr \ ?F) \]
\( \langle \text{proof} \rangle \)

**4.4 Continuity and Induction for Loops**

**theory LoopInduction imports Healthiness Continuity begin**

Showing continuity for loops requires a stronger induction principle than we have used so far, which in turn relies on the continuity of loops (inductively). Thus, the proofs are intertwined, and broken off from the main set of continuity proofs. This result is also essential in showing the sublinearity of loops.

A loop step is monotonic.

**lemma wp-loop-step-mono-trans:**
\[ \text{fixes } body ::'s \ prog \]
\[ \text{assumes } sP : \text{sound } P \]
\[ \text{and } hb : healthy \ (wp \ body) \]
\[ \text{shows } mono-trans \ (\lambda Q s. \ «G» \ s \ast \ wp \ body \ Q \ s + \ « NG» \ s \ast \ P \ s) \]
\( \langle \text{proof} \rangle \)

We can therefore apply the standard fixed-point lemmas to unfold it:

**lemma lfp-wp-loop-unfold:**
\[ \text{fixes } body ::'s \ prog \]
\[ \text{assumes } hb : healthy \ (wp \ body) \]
\[ \text{and } sP : \text{sound } P \]
shows \( \text{lfp-exp} \left( \lambda Q \ s. \langle G \rangle s \ast \text{wp body } Q \ s + \langle N \ G \rangle s \ast P \ s \right) \) = \\
(\lambda s. \langle G \rangle s \ast \text{wp body } (\text{lfp-exp} (\lambda Q \ s. \langle G \rangle s \ast \text{wp body } Q \ s + \langle N \ G \rangle s \ast P \ s)) s + \langle N \ G \rangle s \ast P \ s) \
\langle \text{proof} \rangle

**lemma** \( \text{wp-loop-step-unitary} \): \\
fixes body::'s prog \\
assumes \( h \): healthy \( \text{wp body} \) \\
and \( uP: \text{unitary P} \) and \( uQ: \text{unitary Q} \) \\
shows \( \text{unitary } (\lambda s. \langle G \rangle s \ast \text{wp body } Q \ s + \langle N \ G \rangle s \ast P \ s) \) \\
\langle \text{proof} \rangle

**lemma** \( \text{lfp-loop-unitary} \): \\
fixes body::'s prog \\
assumes \( h \): healthy \( \text{wp body} \) \\
shows \( \text{unitary } (\text{lfp-exp } (\lambda Q \ s. \langle G \rangle s \ast \text{wp body } Q \ s + \langle N \ G \rangle s \ast P \ s)) \) \\
\langle \text{proof} \rangle

From the lattice structure on transformers, we establish a transfinite induction principle for loops. We use this to show a number of properties, particularly subdistributivity, for loops. This proof follows the pattern of lemma \( \text{lfp_ordinal_induct} \) in HOL/Inductive.

**lemma** \( \text{loop-induct} \): \\
fixes body::'s prog \\
assumes \( hwp: \text{healthy } \text{wp body} \) \\
and \( hwlp: \text{nearly-healthy } \text{wlp body} \) \\
— The body must be healthy, both in strict and liberal semantics. \\
and **Limit**: \\
\( \forall \ S. \left[ \forall x \in S. \ P (\text{fst } x); \forall x \in S. \text{ feasible } (\text{fst } x); \forall x \in S. \forall Q. \text{ unitary } Q \Rightarrow \text{ unitary } (\text{snd } x Q) \right] \Rightarrow \ P (\text{Sup-trans } (\text{fst } S)) \) (\( \text{Inf-utrans } (\text{snd } S) \)) \\
— The property holds at limit points. \\
and **IH**: \\
\( \forall t u. \left[ \ P t u; \text{ feasible } t; \langle Q. \text{ unitary } Q \Rightarrow \text{ unitary } (u \ Q) \right] \Rightarrow \ P (\text{wp } (\text{body } \text{:: } \text{Embed } t \langle G \rangle \oplus \text{Skip})) \) \\
\( (\text{wlp } (\text{body } \text{:: } \text{Embed } u \langle G \rangle \oplus \text{Skip})) \) \\
— The inductive step. The property is preserved by a single loop iteration. \\
and **P-equiv**: \\
\( \forall t u. \left[ \ P t u; \text{ equiv-trans } t t'; \text{ equiv-utrans } u u' \right] \Rightarrow P t' u' \) \\
— The property must be preserved by equivalence \\
shows \( P (\text{wp } (\text{do } G \Rightarrow \text{body od})) (\text{wlp } (\text{do } G \Rightarrow \text{body od})) \) \\
— The property can refer to both interpretations simultaneously. The unifier will happily apply the rule to just one or the other, however. \\
\langle \text{proof} \rangle

4.4.1 The Limit of Iterates

The iterates of a loop are its sequence of finite unrollings. We show shortly that this converges on the least fixed point. This is enormously useful, as
we can appeal to various properties of the finite iterates (which will follow by finite induction), which we can then transfer to the limit.

**Definition**

\[ \text{iterates} :: 's \text{ prog} \Rightarrow ('s \Rightarrow \text{bool}) \Rightarrow \text{nat} \Rightarrow 's \text{ trans} \]

**Where**

\[ \text{iterates body } G \ i = ((\lambda x. \text{wp } (\text{body} ;; \text{Embed } x \ « G « \oplus \text{Skip} )) \sim i) (\lambda P \ s. 0) \]

**Lemma** iterates-0 [simp]:

\[ \text{iterates body } G \ 0 = (\lambda P \ s. 0) \]

**Proof**

**Lemma** iterates-Suc [simp]:

\[ \text{iterates body } G \ (\text{Suc } i) = \text{wp } (\text{body} ;; \text{Embed } (\text{iterates body } G \ i) « G « \oplus \text{Skip}) \]

**Proof**

All iterates are healthy.

**Lemma** iterates-healthy:

\[ \text{healthy } (\text{wp } \text{body}) \Rightarrow \text{healthy } (\text{iterates body } G \ i) \]

**Proof**

The iterates are an ascending chain.

**Lemma** iterates-increasing:

**Fixes** body: 's \text{ prog}

**Assumes** hb: healthy (\text{wp body})

**Shows** le-trans (\text{iterates body } G \ i) (\text{iterates body } G \ (\text{Suc } i))

**Proof**

**Lemma** wp-loop-step-bounded:

**Fixes** t: 's \text{ trans} and Q: 's \text{ expect}

**Assumes** nQ: \text{nneg } Q 

and bQ: \text{bounded-by } b \ Q

and ht: healthy t

and hb: healthy (\text{wp body})

**Shows** bounded-by b (\text{wp } (\text{body} ;; \text{Embed } t \ « G « \oplus \text{Skip}) \ Q)

**Proof**

This is the key result: The loop is equivalent to the supremum of its iterates. This proof follows the pattern of lemma continuous_lfp in HOL/Library/Continuity.

**Lemma** lfp-iterates:

**Fixes** body: 's \text{ prog}

**Assumes** hb: healthy (\text{wp body})

and cb: bd-cts (\text{wp body})

**Shows** equiv-trans (\text{wp } (\text{do } G \rightarrow \text{body od}) ((\text{Sup-trans } (\text{range } (\text{iterates body } G))))

(is equiv-trans ?X ?Y)

**Proof**

Therefore, evaluated at a given point (state), the sequence of iterates gives a sequence of real values that converges on that of the loop itself.
4.5. **SUBLINEARITY**

**corollary** loop-iterates:

fixes body:\'_s prog

assumes hb: healthy (wp body)

and cb: bd-cts (wp body)

and sP: sound P

shows (λi. iterates body G i P s) ⟷ wp (do G → body od) P s

⟨proof⟩

The iterates themselves are all continuous.

**lemma** cts-iterates:

fixes body:\'_s prog

assumes hb: healthy (wp body)

and cb: bd-cts (wp body)

shows bd-cts (iterates body G i)

⟨proof⟩

Therefore so is the loop itself.

**lemma** cts-wp-loop:

fixes body:\'_s prog

assumes hb: healthy (wp body)

and cb: bd-cts (wp body)

shows bd-cts (wp do G → body od)

⟨proof⟩

**lemmas** cts-intros =

cts-wp-Abort cts-wp-Skip

cts-wp-Seq cts-wp-PC

cts-wp-DC cts-wp-Embed

cts-wp-Apply cts-wp-SetDC

cts-wp-SetPC cts-wp-Bind

cts-wp-repeat

end

4.5 **Sublinearity**

**theory** Sublinearity imports Embedding Healthiness LoopInduction begin

4.5.1 **Nonrecursive Primitives**

Sublinearity of non-recursive programs is generally straightforward, and follows from the algebraic properties of the underlying operations, together with healthiness.

**lemma** sublinear-wp-Skip:

sublinear (wp Skip)

⟨proof⟩
Lemma sublinear-wp-Abort:
sublinear (wp Abort)
⟨proof⟩

Lemma sublinear-wp-Apply:
sublinear (wp (Apply f))
⟨proof⟩

Lemma sublinear-wp-Seq:
fixes x::'s prog
assumes slx: sublinear (wp x) and sly: sublinear (wp y)
and hx: healthy (wp x) and hy: healthy (wp y)
says sublinear (wp (x ;; y))
⟨proof⟩

Lemma sublinear-wp-PC:
fixes x::'s prog
assumes slx: sublinear (wp x) and sly: sublinear (wp y)
and uP: unitary P
shows sublinear (wp (x ⊕ y))
⟨proof⟩

Lemma sublinear-wp-DC:
fixes x::'s prog
assumes slx: sublinear (wp x) and sly: sublinear (wp y)
says sublinear (wp (x ∩ y))
⟨proof⟩

As for continuity, we insist on a finite support.

Lemma sublinear-wp-SetPC:
fixes p::'a ⇒ 's prog
assumes slp: \(\forall s. a \in \text{supp} (P s) \implies \text{sublinear} (wp (p a))\)
and sum: \(\forall s. (\sum a \in \text{supp} (P s). P s a) \leq 1\)
and nnP: \(\forall s. 0 \leq P s a\)
and fin: \(\forall s. \text{finite} (\text{supp} (P s))\)
says sublinear (wp (SetPC p P))
⟨proof⟩

Lemma sublinear-wp-SetDC:
fixes p::'a ⇒ 's prog
assumes slp: \(\forall s. a \in S s \implies \text{sublinear} (wp (p a))\)
and hp: \(\forall s. a \in S s \implies \text{healthy} (wp (p a))\)
and ne: \(\forall s. S s \neq \{\}\)
says sublinear (wp (SetDC p S))
⟨proof⟩

Lemma sublinear-wp-Embed:
sublinear t ⇒ sublinear (wp (Embed t))
⟨proof⟩
4.5. Sublinearity

Lemma sublinear-wp-repeat:
\[
\begin{align*}
\text{sublinear (wp } p) & ; \text{ healthy (wp } p) \Rightarrow \text{ sublinear (wp (repeat n } p)) \\
\end{align*}
\]
(proof)

Lemma sublinear-wp-Bind:
\[
\begin{align*}
\text{sublinear (wp (a (f s)))} \Rightarrow \text{ sublinear (wp (Bind f a))} \\
\end{align*}
\]
(proof)

4.5.2 Sublinearity for Loops

We break the proof of sublinearity loops into separate proofs of sub-distributivity and sub-additivity. The first follows by transfinite induction.

Lemma sub-distrib-wp-loop:
\[
\text{fixes body: }'s \text{ prog} \\
\text{assumes sdb: sub-distrib (wp body)} \\
\text{and hb: healthy (wp body)} \\
\text{and nhb: nearly-healthy (wp body)} \\
\text{shows sub-distrib (wp (do G } \rightarrow \text{ body od))} \\
\]
(proof)

For sub-additivity, we again use the limit-of-iterates characterisation. Firstly, all iterates are sublinear:

Lemma sub-linear-iterates:
\[
\text{assumes hb: healthy (wp body)} \\
\text{and sb: sublinear (wp body)} \\
\text{shows sublinear (iterates body G i)} \\
\]
(proof)

From this, sub-additivity follows for the limit (i.e. the loop), by appealing to the property at all steps.

Lemma sub-add-wp-loop:
\[
\text{fixes body: }'s \text{ prog} \\
\text{assumes sb: sublinear (wp body)} \\
\text{and cb: bd-cts (wp body)} \\
\text{and hwp: healthy (wp body)} \\
\text{shows sub-add (wp (do G } \rightarrow \text{ body od))} \\
\]
(proof)

Lemma sublinear-wp-loop:
\[
\text{fixes body: }'s \text{ prog} \\
\text{assumes hb: healthy (wp body)} \\
\text{and nhb: nearly-healthy (wp body)} \\
\text{and sb: sublinear (wp body)} \\
\text{and cb: bd-cts (wp body)} \\
\text{shows sublinear (wp (do G } \rightarrow \text{ body od))} \\
\]

end

4.7 Well-Defined Programs.

theory WellDefined imports
  Healthiness
  Sublinearity
  LoopInduction
begin

The definition of a well-defined program collects the various notions of healthiness and well-behavedness that we have so far established: healthiness of the strict and liberal transformers, continuity and sublinearity of the strict transformers, and two new properties. These are that the strict
transformer always lies below the liberal one (i.e. that it is at least as strict, recalling the standard embedding of a predicate), and that expectation conjunction is distributed between then in a particular manner, which will be crucial in establishing the loop rules.

### 4.7.1 Strict Implies Liberal

This establishes the first connection between the strict and liberal interpretations (\(wp\) and \(wlp\)).

**definition**

\[
\text{wp-under-wlp :: 's prog \Rightarrow bool}
\]

**where**

\[
\text{wp-under-wlp prog \equiv \forall P. \text{unitary P \rightarrow wp prog \vdash wlp prog P}}
\]

**lemma** \(\text{wp-under-wlpI[ intro]:}\)

\[
[\forall P. \text{unitary P \Rightarrow wp prog \vdash wlp prog P}] \Rightarrow \text{wp-under-wlp prog}
\]

**lemma** \(\text{wp-under-wlpD[ dest]:}\)

\[
[\text{wp-under-wlp prog; unitary P}] \Rightarrow \text{wp prog \vdash wlp prog P}
\]

**lemma** \(\text{wp-under-le-trans:}\)

\[
\text{wp-under-wlp a \Rightarrow le-utrans (wp a) (wlp a)}
\]

**lemma** \(\text{wp-under-wlp-Abort:}\)

\[
\text{wp-under-wlp Abort}
\]

**lemma** \(\text{wp-under-wlp-Skip:}\)

\[
\text{wp-under-wlp Skip}
\]

**lemma** \(\text{wp-under-wlp-Apply:}\)

\[
\text{wp-under-wlp (Apply f)}
\]

**lemma** \(\text{wp-under-wlp-Seq:}\)

**assumes** \(h-wlp-a: \text{nearly-healthy (wlp a)}\)

**and** \(h-wp-b: \text{healthy (wp b)}\)

**and** \(h-wlp-b: \text{nearly-healthy (wlp b)}\)

**and** \(wp-u-a: \text{wp-under-wlp a}\)

**and** \(wp-u-b: \text{wp-under-wlp b}\)

**shows** \(\text{wp-under-wlp (a ;; b)}\)

**lemma** \(\text{wp-under-wlp-PC:}\)
4.7. WELL-DEFINED PROGRAMS.

assumes $h$-wp-a: healthy $(wp\,a)$

\section{The Loop Rules}

\textbf{Theory Loops imports \textit{WellDefined} begin}

\textbf{Given a well-defined body, we can annotate a loop using an invariant, just as in the classical setting.}

\subsection{Liberal and Strict Invariants.}

A probabilistic invariant generalises a boolean one: it \textit{entails} itself, given the loop guard.

\textbf{Definition}
\[
\text{wp-inv :: } ('s \Rightarrow \text{bool}) \Rightarrow 's \text{ prog } \Rightarrow ('s \Rightarrow \text{real}) \Rightarrow \text{bool}
\]

\textbf{Where}
4.8. THE LOOP RULES

\[ \text{wp-inv } G \text{ body } I \leftrightarrow (\forall s. \langle G \rangle s * I s \leq \text{wp body } I s) \]

**lemma** \( \text{wp-invI} \):
\[ \bigwedge I. (\forall s. \langle G \rangle s * I s \leq \text{wp body } I s) \implies \text{wp-inv } G \text{ body } I \]

**definition**
\[ \text{wlp-inv} :: \langle 's \Rightarrow \text{bool} \rangle \Rightarrow \langle 's \text{ prog} \Rightarrow \langle 's \Rightarrow \text{real} \rangle \Rightarrow \text{bool} \]

**where**
\[ \text{wlp-inv } G \text{ body } I \leftrightarrow (\forall s. \langle G \rangle s * I s \leq \text{wlp body } I s) \]

**lemma** \( \text{wlp-invI} \):
\[ \bigwedge I. (\forall s. \langle G \rangle s * I s \leq \text{wlp body } I s) \implies \text{wlp-inv } G \text{ body } I \]

For standard invariants, the multiplication reduces to conjunction.

**lemma** \( \text{wp-inv-stdD} \):
\[ \text{assumes } \text{inv}: \text{wp-inv } G \text{ body } I, \text{ and } \text{hb}: \text{healthy (wp body) } \]
\[ \text{shows } \langle G \rangle \&\& \langle I \rangle \triangleright wp \text{ body } I \]

4.8.2 Partial Correctness

**lemma** \( \text{wlp-Loop} \):
\[ \text{assumes } \text{wd}: \text{well-def body}, \text{ and } \text{ui}: \text{unitary } I, \text{ and } \text{inv}: \text{wlp-inv } G \text{ body } I \]
\[ \text{shows } I \leq \text{wlp do } G \rightarrow \text{body od } (\lambda s. \langle N G \rangle s * I s) \]
\[ (\text{is } I \leq \text{wlp do } G \rightarrow \text{body od } ?P) \]

4.8.3 Total Correctness

The first total correctness lemma for loops which terminate with probability 1[McIver and Morgan, 2004, Lemma 7.3.1, §7, p. 186].

**lemma** \( \text{wp-Loop} \):
\[ \text{assumes } \text{wd}: \text{well-def body}, \text{ and } \text{ui}: \text{unitary } I, \text{ and } \text{inv}: \text{wlp-inv } G \text{ body } I \]
\[ \text{shows } I \&\& \text{ wp } (\text{do } G \rightarrow \text{body od}) (\lambda s. 1) \triangleright wp \ (\text{do } G \rightarrow \text{body od}) (\lambda s. \langle N G \rangle s * I s) \]
(is I && ?T ⊢ wp ?loop ?X)

4.8.4 Unfolding

lemma wp-loop-unfold:
  fixes body :: 's prog
  assumes sP: sound P
  and h: healthy (wp body)
  shows wp (do G → body od) P =
    (λs. «N G» s * P s + «G» s * wp body (wp (do G → body od) P) s)

lemma wp-loop-nguard:
[ healthy (wp body); sound P; ¬ G s ] ⇒ wp do G → body od P s = P s

lemma wp-loop-guard:
[ healthy (wp body); sound P; G s ] ⇒ wp do G → body od P s = wp (body ;; do G → body od) P s

end

4.9 The Algebra of pGCL

theory Algebra imports WellDefined begin

Programs in pGCL have a rich algebraic structure, largely mirroring that for GCL. We show that programs form a lattice under refinement, with a ▽ b and a ∪ b as the meet and join operators, respectively. We also take advantage of the algebraic structure to establish a framework for the modular decomposition of proofs.

4.9.1 Program Refinement

Refinement in pGCL relates to refinement in GCL exactly as probabilistic entailment relates to implication. It turns out to have a very similar algebra, the rules of which we establish shortly.

definition refines :: 's prog ⇒ 's prog ⇒ bool (infix ⊑ 70)
where
  prog ⊑ prog' ≡ ∀ P. sound P → wp prog P ⊢ wp prog' P

lemma refinesI[intro]:
[ ▽ P. sound P → wp prog P ⊢ wp prog' P ] ⇒ prog ⊑ prog'
4.9. THE ALGEBRA OF PGCL

lemma refinesD[dest]:
\[
\begin{array}{l}
\text{[ prog } \sqsubseteq \text{ progs}; \text{ sound } P ] \implies \wp \text{ prog } P \not\models \wp \text{ progs } P
\end{array}
\]

(proof)

The equivalence relation below will turn out to be that induced by refinement. It is also the application of equiv-trans to the weakest precondition.

definition
pequiv :: 's prog \Rightarrow 's prog \Rightarrow bool (infix \simeq 70)
where
prog \simeq progs \equiv \forall P. \text{ sound } P \implies \wp \text{ prog } P = \wp \text{ progs } P

lemma pequivI[intro]:
\[
\begin{array}{l}
\text{[ } \forall P. \text{ sound } P \implies \wp \text{ prog } P = \wp \text{ progs } P \text{ ] } \implies \text{ prog } \simeq \text{ progs }'
\end{array}
\]

(proof)

lemma pequivD[dest,simp]:
\[
\begin{array}{l}
\text{[ prog } \simeq \text{ progs }'; \text{ sound } P ] \implies \wp \text{ prog } P = \wp \text{ progs } P
\end{array}
\]

(proof)

lemma pequiv-equiv-trans:
\[
\begin{array}{l}
a \simeq b \iff \text{ equiv-trans } (wp a) (wp b)
\end{array}
\]

(proof)

4.9.2 Simple Identities

The following identities involve only the primitive operations as defined in Section 4.1.1, and refinement as defined above.

Laws following from the basic arithmetic of the operators separately

lemma DC-comm[ac-simps]:
\[
\begin{array}{l}
a \sqcap b = b \sqcap a
\end{array}
\]

(proof)

lemma DC-assoc[ac-simps]:
\[
\begin{array}{l}
a \sqcap (b \sqcap c) = (a \sqcap b) \sqcap c
\end{array}
\]

(proof)

lemma DC-idem:
\[
\begin{array}{l}
a \sqcap a = a
\end{array}
\]

(proof)

lemma AC-comm[ac-simps]:
\[
\begin{array}{l}
a \sqcup b = b \sqcup a
\end{array}
\]

(proof)
\textbf{lemma} AC-assoc[ac-simps]:
\[ a \biguplus (b \biguplus c) = (a \biguplus b) \biguplus c \]
\langle proof \rangle

\textbf{lemma} AC-idem:
\[ a \biguplus a = a \]
\langle proof \rangle

\textbf{lemma} PC-quasi-comm:
\[ a \iosis\ b = b (\lambda s. 1 - p s) \iosis\ a \]
\langle proof \rangle

\textbf{lemma} PC-idem:
\[ a \iosis\ a = a \]
\langle proof \rangle

\textbf{lemma} Seq-assoc[ac-simps]:
\[ A \;;; (B \;;; C) = A \;;; B \;;; C \]
\langle proof \rangle

\textbf{lemma} Abort-refines[intro]:
\[ \text{well-def } a \implies \text{Abort } \subseteq a \]
\langle proof \rangle

\textbf{Laws relating demonic choice and refinement}

\textbf{lemma} left-refines-DC:
\[ (a \bigcap b) \subseteq a \]
\langle proof \rangle

\textbf{lemma} right-refines-DC:
\[ (a \bigcap b) \subseteq b \]
\langle proof \rangle

\textbf{lemma} DC-refines:
\[ \text{fixes } a::'s \text{ prog and } b \text{ and } c \]
\[ \text{assumes } \text{rab: } a \subseteq b \text{ and } \text{rac: } a \subseteq c \]
\[ \text{shows } a \subseteq (b \bigcap c) \]
\langle proof \rangle

\textbf{lemma} DC-mono:
\[ \text{fixes } a::'s \text{ prog} \]
\[ \text{assumes } \text{rab: } a \subseteq b \text{ and } \text{rcd: } c \subseteq d \]
\[ \text{shows } (a \bigcap c) \subseteq (b \bigcap d) \]
\langle proof \rangle

\textbf{Laws relating angelic choice and refinement}

\textbf{lemma} left-refines-AC:
\[ a \subseteq (a \biguplus b) \]
4.9. THE ALGEBRA OF PGCL

\[\text{proof}\]

**Lemma** right-refines-AC:
\[b \sqsubseteq (a \cup b)\]
\[\text{proof}\]

**Lemma** AC-refines:
- **Fixes** \(a::'s\ prog\) and \(b\) and \(c\)
- **Assumes** rac: \(a \sqsubseteq c\) and rbc: \(b \sqsubseteq c\)
- **Shows** \((a \cup b) \sqsubseteq c\)
\[\text{proof}\]

**Lemma** AC-mono:
- **Fixes** \(a::'s\ prog\)
- **Assumes** rab: \(a \sqsubseteq b\) and rcd: \(c \sqsubseteq d\)
- **Shows** \((a \cup c) \sqsubseteq (b \cup d)\)
\[\text{proof}\]

Laws depending on the arithmetic of \(a \oplus b\) and \(a \sqcap b\) together

**Lemma** DC-refines-PC:
- **Assumes** unit: \(\text{unitary } p\)
- **Shows** \((a \sqcap b) \sqsubseteq (a \oplus b)\)
\[\text{proof}\]

Laws depending on the arithmetic of \(a \oplus b\) and \(a \cup b\) together

**Lemma** PC-refines-AC:
- **Assumes** unit: \(\text{unitary } p\)
- **Shows** \((a \oplus b) \sqsubseteq (a \cup b)\)
\[\text{proof}\]

Laws depending on the arithmetic of \(a \sqcup b\) and \(a \sqcap b\) together

**Lemma** DC-refines-AC:
\[(a \sqcap b) \sqsubseteq (a \sqcup b)\]
\[\text{proof}\]

Laws Involving Refinement and Equivalence

**Lemma** pr-trans[trans]:
- **Fixes** \(A::'a\ prog\)
- **Assumes** prAB: \(A \sqsubseteq B\)
  - and prBC: \(B \sqsubseteq C\)
- **Shows** \(A \sqsubseteq C\)
\[\text{proof}\]

**Lemma** pequiv-refl[intro,simp]:
\[a \simeq a\]
\[\text{proof}\]
Refinement induces equivalence by antisymmetry:

**lemma** pequiv-antisym:
\[
\begin{array}{l}
[a \sqsubseteq b; b \sqsubseteq a] \Rightarrow a \simeq b
\end{array}
\]

\langle proof \rangle

**4.9.3 Deterministic Programs are Maximal**

Any sub-additive refinement of a deterministic program is in fact an equivalence. Deterministic programs are thus maximal (under the refinement order) among sub-additive programs.

**lemma** refines-determ:
\[
\begin{array}{l}
\text{fixes } a::'s \text{ prog}
\end{array}
\]
\[
\begin{array}{l}
\text{assumes } da: \text{ determ } (wp a)
\end{array}
\]
\[
\begin{array}{l}
\text{and } wa: \text{ well-def } a
\end{array}
\]
\[
\begin{array}{l}
\text{and } wb: \text{ well-def } b
\end{array}
\]
\[
\begin{array}{l}
\text{and } dr: a \sqsubseteq b
\end{array}
\]
\[
\begin{array}{l}
\text{shows } a \simeq b
\end{array}
\]

\langle proof \rangle
4.9.4 The Algebraic Structure of Refinement

Well-defined programs form a half-bounded semilattice under refinement, where Abort is bottom, and \( a \sqcap b \) is \( \text{inf} \). There is no unique top element, but all fully-deterministic programs are maximal.

The type that we construct here is not especially useful, but serves as a convenient way to express this result.

\[
\text{quotient-type } 's \text{ prog} = \\
's \text{ prog} / \text{ partial} : \lambda a \quad b. \quad a \simeq b \land \text{well-def } a \land \text{well-def } b
\]

\[
\text{instantiation program ::= (type) semilattice-inf begin} \\
\text{lift-definition} \\
\text{less-eq-program ::= 'a program } \Rightarrow 'a \text{ program } \Rightarrow \text{bool is refines} \\
\text{⟨proof⟩}
\]

\[
\text{lift-definition} \\
\text{less-program ::= 'a program } \Rightarrow 'a \text{ program } \Rightarrow \text{bool} \\
\text{is } \lambda a \quad b. \quad a \subseteq b \land \neg b \subseteq a \\
\text{⟨proof⟩}
\]

\[
\text{lift-definition} \\
\text{inf-program ::= 'a program } \Rightarrow 'a \text{ program } \Rightarrow 'a \text{ program is DC} \\
\text{⟨proof⟩}
\]

\[
\text{instance} \\
\text{⟨proof⟩}
\end
\]

\[
\text{instantiation program ::= (type) bot begin} \\
\text{lift-definition} \\
\text{bot-program ::= 'a program is Abort} \\
\text{⟨proof⟩}
\]

\[
\text{instance } \langle \text{proof} \rangle
\end
\]

\[
\text{lemma eq-det: } \land a \quad b.'s \text{ prog. } [a \simeq b; \text{determin wp } a] \implies \text{determin wp } b \\
\text{⟨proof⟩}
\]

\[
\text{lift-definition} \\
\text{pdeterm ::= 's program } \Rightarrow \text{bool} \\
\text{is } \lambda a. \quad \text{determin wp } a \\
\text{⟨proof⟩}
\]

\[
\text{lemma determin-maximal:} \\
[\text{pdeterm } a; a \leq x ] \implies a = x \\
\text{⟨proof⟩}
\]
4.9.5 Data Refinement

A projective data refinement construction for pGCL. By projective, we mean that the abstract state is always a function ($\varphi$) of the concrete state. Refinement may be predicated ($G$) on the state.

**definition**

drefines :: (\'b \Rightarrow \'a) \Rightarrow \'b prog \Rightarrow \'a prog \Rightarrow bool

**where**

drefines $\varphi$ $G$ $A$ $B$ $\equiv \forall P Q. (\text{unitary } P \land \text{unitary } Q \land (P \vdash \text{wp } A \ Q)) \rightarrow (\langle G \rangle \land \land (P \circ \varphi) \vdash \text{wp } B \ (Q \circ \varphi))$

**lemma** drefinesD[dest]:

\[
\begin{array}{l}
\text{assumes } dr: \ drefines \varphi \ G \ A \ B \\
\text{and } uP: \ \text{unitary } P \\
\text{and } uQ: \ \text{unitary } Q \\
\text{and } wpA: \ P \vdash \text{wp } A \ Q \\
\text{and } G: \ G \ s \\
\end{array}
\]

shows \((P \circ \varphi) \ s \leq \text{wp } B \ (Q \circ \varphi) \ s\)

\langle proof \rangle

We can alternatively use $G$ as an assumption:

**lemma** drefinesD2:

\[
\begin{array}{l}
\text{assumes } dr: \ drefines \varphi \ G \ a \ b \\
\text{and } G: \ G \ s \\
\text{and } uQ: \ \text{unitary } Q \\
\text{and } wa: \ \text{well-def } a \\
\end{array}
\]

shows $\text{wp } a \ Q \ (\varphi \ s) \leq \text{wp } b \ (Q \circ \varphi) \ s$

\langle proof \rangle

This additional form is sometimes useful:

**lemma** drefinesD3:

\[
\begin{array}{l}
\text{assumes } dr: \ drefines \varphi \ G \ a \ b \\
\text{and } G: \ G \ s \\
\text{and } uQ: \ \text{unitary } Q \\
\text{and } wa: \ \text{well-def } a \\
\end{array}
\]

shows $\text{wp } a \ Q \ (\varphi \ s) \leq \text{wp } b \ (Q \circ \varphi) \ s$

\langle proof \rangle

**lemma** drefinesI[intro]:

\[
\begin{array}{l}
\text{assumes } \forall P Q. (\text{unitary } P \land \text{unitary } Q \land (P \vdash \text{wp } A \ Q)) \rightarrow (\langle G \rangle \land \land (P \circ \varphi) \vdash \text{wp } B \ (Q \circ \varphi))
\end{array}
\]

\langle proof \rangle

Use $G$ as an assumption, when showing refinement:

**lemma** drefinesI2:

\[
\begin{array}{l}
\text{fixes } A::\'a \ prog \\
\text{and } B::\'b \ prog \\
\text{and } \varphi::\'b \Rightarrow \'a \\
\text{and } G::\'b \Rightarrow \text{bool} \\
\text{assumes } wB: \ \text{well-def } B \\
\end{array}
\]

\langle proof \rangle
4.9. THE ALGEBRA OF PGCL

\[ \bigwedge P Q s. \left[ \text{unitary } P; \text{unitary } Q; \right. \]
\[ G s; P \vdash \text{wp } A Q \big] \Longrightarrow (P o \varphi) s \leq \text{wp } B (Q o \varphi) s \]
shows drefines \( \varphi \ G A B \)

(\text{proof})

**lemma dr-strengthen-guard:**

\text{fixes } a::'s \text{ prog and } b::'t \text{ prog}
\text{assumes } fg: \bigwedge s. F s \Longrightarrow G s
\text{and } drab: \text{drefines } \varphi \ G a b

shows drefines \( \varphi \ F a b \)

(\text{proof})

Probabilistic correspondence, \text{pcorres}, is equality on distribution transformers, modulo a guard. It is the analogue, for data refinement, of program equivalence for program refinement.

**definition**

\text{pcorres }:: \left( 'b \Rightarrow 'a \right) \Rightarrow \left( 'b \Rightarrow \text{bool} \right) \Rightarrow 'a \text{ prog } \Rightarrow 'b \text{ prog } \Rightarrow \text{bool}

\text{where}

\text{pcorres } \varphi \ G A B \leftarrow \leftarrow
\left( \forall Q. \text{unitary } Q \right. \Longrightarrow \left. \langle G \rangle \ & \& (\text{wp } A Q o \varphi) = \langle G \rangle \ & \& \text{wp } B (Q o \varphi) \right)

**lemma pcorresI:**

\[ \left[ \text{pcorres } \varphi \ G A B \right] \Longrightarrow \left[ \text{wp } A Q (\varphi s) = \text{wp } B (Q o \varphi) s \right. \]

(\text{proof})

Often easier to use, as it allows one to assume the precondition.

**lemma pcorresI2[intro]:**

\text{fixes } A::'a \text{ prog and } B::'b \text{ prog}
\text{assumes withG: } \bigwedge Q s. \left[ \text{unitary } Q; G s \right. \big] \Longrightarrow \left. \text{wp } A Q (\varphi s) = \text{wp } B (Q o \varphi) s \right.
\text{and } wA: \text{well-def } A
\text{and } wB: \text{well-def } B

shows pcorres \( \varphi \ G A B \)

(\text{proof})

**lemma pcorresD:**

\[ \left[ \text{pcorres } \varphi \ G A B; \text{unitary } Q \right] \Longrightarrow \langle G \rangle \ & \& (\text{wp } A Q (\varphi) o \varphi) = \langle G \rangle \ & \& \text{wp } B (Q o \varphi) \]

(\text{proof})

Again, easier to use if the precondition is known to hold.

**lemma pcorresD2:**

\text{assumes } pc: \text{pcorres } \varphi \ G A B
\text{and } uQ: \text{unitary } Q
\text{and } wA: \text{well-def } A \text{ and } wB: \text{well-def } B
\text{and } G: G s

shows wp A Q (\varphi s) = wp B (Q o \varphi) s

(\text{proof})
4.9.6 The Algebra of Data Refinement

Program refinement implies a trivial data refinement:

**Lemma** refines-drefines:

fixes $a::'s prog$

assumes $rab: a \sqsubseteq b$ and $wb: \text{well-def } b$

shows drefines $(\lambda s. s) G a b$

(proof)

Data refinement is transitive:

**Lemma** dr-trans[trans]:

fixes $A::'a prog$ and $B::'b prog$ and $C::'c prog$

assumes $drAB: \text{drefines } \varphi G A B$

and $drBC: \text{drefines } \varphi' G' B C$

and $Gimp: \forall s. G' s \Rightarrow G (\varphi' s)$

shows drefines $(\varphi \circ \varphi') G' A C$

(proof)

Data refinement composes with program refinement:

**Lemma** pr-dr-trans[trans]:

assumes $prAB: A \sqsubseteq B$

and $drBC: \text{drefines } \varphi G B C$

shows drefines $\varphi G A C$

(proof)

**Lemma** dr-pr-trans:

assumes $drAB: \text{drefines } \varphi G A B$

assumes $prBC: B \sqsubseteq C$

shows drefines $\varphi G A C$

(proof)

If the projection $\varphi$ commutes with the transformer, then data refinement is reflexive:

**Lemma** dr-refl:

assumes $wa: \text{well-def } a$

and $comm: \forall Q. \text{unitary } Q \Rightarrow wp a Q o \varphi \vdash wp a (Q o \varphi)$

shows drefines $\varphi G a a$

(proof)

Correspondence implies data refinement

**Lemma** pcorres-drefine:

assumes $corres: \text{pcorres } \varphi G A C$

and $wC: \text{well-def } C$

shows drefines $\varphi G A C$

(proof)

Any data refinement of a deterministic program is correspondence. This is the analogous result to that relating program refinement and equivalence.
4.9. THE ALGEBRA OF PGCL

lemma \texttt{drefines\_determ}:
\begin{align*}
\text{fixes } &a::'a\text{ \texttt{prog}} \text{ and } b::'b\text{ \texttt{prog}} \\
\text{assumes } &da: \text{ determ (wp a)} \\
&\text{and } wa: \text{ well-def a} \\
&\text{and } wb: \text{ well-def b} \\
&\text{and } dr: \text{ drefines } \varphi \ G \ a \ b \\
\text{shows } &\texttt{pcorres } \varphi \ G \ a \ b
\end{align*}

The proof follows exactly the same form as that for program refinement: Assuming that correspondence doesn’t hold, we show that \texttt{wp b} is not feasible, and thus not healthy, contradicting the assumption.

\langle \text{proof} \rangle

4.9.7 Structural Rules for Correspondence

lemma \texttt{pcorres\_Skip}:
\texttt{pcorres } \varphi \ G \ \texttt{Skip} \ \texttt{Skip}

\langle \text{proof} \rangle

Correspondence composes over sequential composition.

lemma \texttt{pcorres\_Seq}:
\begin{align*}
\text{fixes } &A::'b\text{ \texttt{prog}} \text{ and } B::'c\text{ \texttt{prog}} \\
&\text{and } C::'b\text{ \texttt{prog}} \text{ and } D::'c\text{ \texttt{prog}} \\
&\text{and } \varphi::'c \Rightarrow 'b \\
\text{assumes } &\texttt{pcAB} : \text{ pcorres } \varphi \ G \ A \ B \\
&\text{and } \texttt{pcCD} : \text{ pcorres } \varphi \ H \ C \ D \\
&\text{and } wA: \text{ well-def } A \text{ and } wB: \text{ well-def } B \\
&\text{and } wC: \text{ well-def } C \text{ and } wD: \text{ well-def } D \\
&\text{and } p3p2: \bigwedge Q. \text{ unitary } Q \implies \langle I \rangle \ \& \ wp \ B \ Q = wp \ B \ (\langle H \rangle \ \& \ Q) \\
&\text{and } p1p3: \bigwedge s. \ G \ s \implies I \ s \\
\text{shows } &\texttt{pcorres } \varphi \ G \ (A;;C) \ (B;;D)
\end{align*}

\langle \text{proof} \rangle

4.9.8 Structural Rules for Data Refinement

lemma \texttt{dr\_Skip}:
\begin{align*}
\text{fixes } &\varphi::'c \Rightarrow 'b \\
\text{shows } &\texttt{drefines } \varphi \ G \ \texttt{Skip} \ \texttt{Skip}
\end{align*}

\langle \text{proof} \rangle

lemma \texttt{dr\_Abort}:
\begin{align*}
\text{fixes } &\varphi::'c \Rightarrow 'b \\
\text{shows } &\texttt{drefines } \varphi \ G \ \texttt{Abort} \ \texttt{Abort}
\end{align*}

\langle \text{proof} \rangle

lemma \texttt{dr\_Apply}:
\begin{align*}
\text{fixes } &\varphi::'c \Rightarrow 'b \\
\text{assumes } &\text{commutes: } f \circ \varphi = \varphi \circ g \\
\text{shows } &\texttt{drefines } \varphi \ G \ (\texttt{Apply } f) \ (\texttt{Apply } g)
\end{align*}

\langle \text{proof} \rangle
\]
4.10. STRUCTURED REASONING

**lemma** `wp-SetPC-split`:  
\[
\begin{align*}
\forall x \in \text{supp}(p) & \Rightarrow P x \vdash wp(f x) Q; \forall s. \text{nneg}(p) \] \] \\
(\lambda s. \sum x \in \text{supp}(p). p x * P x s) \vdash wp(\text{SetPC} f p) Q
\end{align*}
\]

**proof**

**lemma** `wlp-SetPC-split`:  
\[
\begin{align*}
\forall x \in \text{supp}(p) & \Rightarrow P x \vdash \text{wlp}(f x) Q; \forall s. \text{nneg}(p) \] \] \\
(\lambda s. \sum x \in \text{supp}(p). p x * P x s) \vdash \text{wlp}(\text{SetPC} f p) Q
\end{align*}
\]

**proof**

**lemma** `wp-SetDC-split`:  
\[
\begin{align*}
\forall s x. x \in S & \Rightarrow P x \vdash wp(f x) Q; \forall s. S s \neq \{} \] \] \\
P \vdash wp(\text{SetDC} f S) Q
\end{align*}
\]

**proof**

**lemma** `wlp-SetDC-split`:  
\[
\begin{align*}
\forall s x. x \in S & \Rightarrow P x \vdash \text{wlp}(f x) Q; \forall s. S s \neq \{} \] \] \\
P \vdash \text{wlp}(\text{SetDC} f S) Q
\end{align*}
\]

**proof**

**lemma** `wp-SetDC`:  
assumes `wp`: \[ \forall s x. x \in S \Rightarrow P x \vdash wp(f x) Q \]  
and \( nc: \forall s. S s \neq \{} \)  
and \( sp: \forall x. \text{sound}(P x) \)  
shows \( (\lambda s. \text{Inf}((\lambda x. P x s) * S s)) \vdash wp(\text{SetDC} f S) Q \)

**proof**

**lemma** `wlp-SetDC`:  
assumes `wp`: \[ \forall s x. x \in S \Rightarrow P x \vdash \text{wlp}(f x) Q \]  
and \( nc: \forall s. S s \neq \{} \)  
and \( sp: \forall x. \text{sound}(P x) \)  
shows \( (\lambda s. \text{Inf}((\lambda x. P x s) * S s)) \vdash \text{wlp}(\text{SetDC} f S) Q \)

**proof**

**lemma** `wp-Embed`:  
P \vdash t Q \Rightarrow P \vdash wp(\text{Embed} t) Q

**proof**

**lemma** `wlp-Embed`:  
P \vdash t Q \Rightarrow P \vdash \text{wlp}(\text{Embed} t) Q

**proof**

**lemma** `wp-Bind`:  
[ \[ \forall s. P s \leq wp(a(f s)) Q s \] \] \Rightarrow P \vdash wp(\text{Bind} f a) Q

**proof**

**lemma** `wlp-Bind`:  
[ \[ \forall s. P s \leq wlp(a(f s)) Q s \] \] \Rightarrow P \vdash wlp(\text{Bind} f a) Q

**proof**
CHAPTER 4. THE PGCL LANGUAGE

**Lemma** `wp-repeat`:

\[
\begin{align*}
P \vdash wp a Q; & Q \vdash wp (repeat n a) R; \\
\text{well-def } a; & \text{sound } Q; \text{ sound } R \implies P \vdash wp (repeat (Suc n) a) R
\end{align*}
\]

\[(proof)\]

**Lemma** `wlp-repeat`:

\[
\begin{align*}
P \vdash wlp a Q; & Q \vdash wlp (repeat n a) R; \\
\text{well-def } a; & \text{unitary } Q; \text{ unitary } R \implies P \vdash wlp (repeat (Suc n) a) R
\end{align*}
\]

\[(proof)\]

Note that the loop rules presented in section Section 4.8 are of the same form, and would belong here, had they not already been stated.

The following rules are specialisations of those for general transformers, and are easier for the unifier to match.

**Lemmas** `wp-strengthen-post`:

\[
\text{entails-strengthen-post}[\text{where } t=wp a \text{ for } a]
\]

**Lemma** `wlp-strengthen-post`:

\[
\begin{align*}
P \vdash wlp a Q \implies \text{nearly-healthy } (wlp a) \implies \text{unitary } R \implies Q \vdash R \implies \text{unitary } Q \implies P \vdash wlp a R
\end{align*}
\]

\[(proof)\]

**Lemmas** `wp-weaken-pre`:

\[
\text{entails-weaken-pre}[\text{where } t=wp a \text{ for } a]
\]

**Lemmas** `wlp-weaken-pre`:

\[
\text{entails-weaken-pre}[\text{where } t=wlp a \text{ for } a]
\]

**Lemmas** `wp-scale`:

\[
\text{entails-scale}[\text{where } t=wp a \text{ for } a, \text{OF - well-def-wp-healthy}]
\]

4.10.2 Algebraic Decomposition

Refinement is a powerful tool for decomposition, belied by the simplicity of the rule. This is an *axiomatic* formulation of refinement (all annotations of the \(a\) are annotations of \(b\)), rather than an operational version (all traces of \(b\) are traces of \(a\)).

**Lemma** `wp-refines`:

\[
\begin{align*}
[a \sqsubseteq b; & P \vdash wp a Q; \text{ sound } Q \implies P \vdash wp b Q
\end{align*}
\]

\[(proof)\]

**Lemmas** `wp-drefines` = `drefinesD`
4.10.3 Hoare triples

The Hoare triple, or validity predicate, is logically equivalent to the weakestprecondition entailment form. The benefit is that it allows us to define transitivity rules for computational (also/finally) reasoning.

```
definition wp-valid :: ('a ⇒ real) ⇒ 'a prog ⇒ ('a ⇒ real) ⇒ bool (\{\} - \{\} p)
where
wp-valid P prog Q ≡ P ⊢ wp prog Q
```

```
lemma wp-validI:
P ⊢ wp prog Q ⇒ \{P\} prog \{Q\} p
⟨proof⟩
```

```
lemma wp-validD:
\{P\} prog \{Q\} p ⇒ P ⊢ wp prog Q
⟨proof⟩
```

```
lemma valid-Seq:
[ \{P\} a \{Q\} p; \{Q\} b \{R\} p; well-def a; well-def b; sound Q; sound R ] ⇒
\{P\} a ;; b \{R\} p
⟨proof⟩
```

We make it available to the computational reasoner:

```
declare valid-Seq[trans]
```

end

4.11 Loop Termination

theory Termination imports Embedding StructuredReasoning Loops begin

Termination for loops can be shown by classical means (using a variant, or a measure function), or by probabilistic means: We only need that the loop terminates with probability one.

4.11.1 Trivial Termination

A maximal transformer (program) doesn’t affect termination. This is essentially saying that such a program doesn’t abort (or diverge).

```
lemma maximal-Seq-term:
fixes r::'s prog and s::'s prog
assumes mr: maximal (wp r)
    and ws: well-def s
    and ts: (\λ s. 1) ⊢ wp s (\λ s. 1)
shows (\λ s. 1) ⊢ wp (r ;; s) (\λ s. 1)
⟨proof⟩
```

From any state where the guard does not hold, a loop terminates in a single step.

**lemma** term-onestep:
- **assumes** wb: well-def body
- **shows** «N G» ⊬ wp G → body od (λs. 1)

4.11.2 Classical Termination

The first non-trivial termination result is quite standard: If we can provide a natural-number-valued measure, that decreases on every iteration, and implies termination on reaching zero, the loop terminates.

**lemma** loop-term-nat-measure-noinv:
- **fixes** m :: 's ⇒ nat and body :: 's prog
- **assumes** wb: well-def body
- and guard: (λs. m s = 0 → ¬ G s)
- and variant: (λn. «λs. m s = Suc n» ⊬ wp body «λs. m s = n»)
- **shows** «λs. 1» ⊬ wp G → body od (λs. 1)

This version allows progress to depend on an invariant. Termination is then determined by the invariant’s value in the initial state.

**lemma** loop-term-nat-measure:
- **fixes** m :: 's ⇒ nat and body :: 's prog
- **assumes** wb: well-def body
- and guard: (λs. m s = 0 → ¬ G s)
- and variant: (λn. «λs. m s = Suc n» & «I» ⊬ wp body «λs. m s = n»)
- and inv: wp-inv G body «I»
- **shows** «I» ⊬ wp G → body od (λs. 1)

4.11.3 Probabilistic Termination

Any loop that has a non-zero chance of terminating after each step terminates with probability 1.

**lemma** termination-0-1:
- **fixes** body :: 's prog
- **assumes** wb: well-def body
- and onestep: (λs. p) ⊬ wp body «N G»
- and nzp: 0 < p
- and mb: maximal (wp body)
- **shows** «λs. 1» ⊬ wp G → body od (λs. 1)

end
